TABLE OF CONTENTS

Contents

INTRODUCTION

The Nizi property comprises an adularia-sericite, low sulphidation, low sulphide type, epithermal gold prospect located in north central British Columbia.

Gold – silver sulphide mineralization occurs in a microcrystalline to fine-grained quartz vein and stockwork system that cuts a sequence of felsic to mafic volcanic flows and pyroclastic rocks. These rocks, known informally as the Nizi volcanic sequence, are exposed in a southeasterly tapering, fault-bounded area and are inferred to be Cretaceous-Tertiary in age (Plint et al., 1998).

A 4-person crew mobilized to the project from September 10 to 14, 2021. The work was conducted out of a fly camp on Zinc Lake, located on the central section of the tenement area.

The main objective of the program was to complete a soil sampling grid on the south side of a ridge running approximately east-west across the central license area. This ridge was the site of limited drilling in the 1990s, which yielded 5.68 g/t Au over 13.77m and 3.54 g/t Au plus 27.21 g/t Ag over 6.1m.

Soil sampling reported by Kaminak Gold in 2009 detected anomalous values of gold on the south side of this ridge. Reported values ranged up to 724.2 ppb Au. A total of 101 samples were collected over a grid at 50 meter spacing located to the west of the previous sampling, to test for extensions of gold-in-soil anomalies.

Limited rock sampling was also conducted along the east-west ridge, as well as a north-south trending ridge located on the east side of the tenement area. Crews traversed these ridges, taking samples at regular intervals. A total of 26 samples were collected.

All samples were assayed for multi-element geochemistry at ALS Laboratories in Kamloops and Vancouver, British Columbia.

LOCATION & ACCESS

The Nizi property is located 130 km southwest of the town of Watson Lake, Yukon, 85 km northwest of the town of Dease Lake, British Columbia and 60 km southwest of the settlement of Cassiar. The claims lie within the Liard Mining District, on NTS map sheets 104/I 95, 96, centred approximately at latitude 58 degrees 58'35"N and longitude 128 degrees 50'52"W.

The Stewart-Cassiar Highway passes approximately 50km west of the property. Access is via helicopter from Dease Lake. Tundra Helicopters out of Watson Lake provides service to the area.

Figure 1: Location of Nizi Lake property in BC Province

PHYSIOGRAPHY & CLIMATE

The Nizi property lies in the Stikine Ranges of the Cassiar Mountains. Elevations range from approximately 1100 m to 2000 m above sea level within the property. Treeline starts between 1,450 m and 1,800 metres asl, consisting mostly of low trees and shrubs. Slopes vary from 10 to 70 degrees but average 35-40 degrees. Outcrop exposure is good on ridgetops but declines significantly approaching and below the treeline.

The Nizi area is bounded to the north by the Rapid River and Four Mile River, to the west and east by tributaries of these. There are three significant lakes in the region, potentially suitable for landing float planes: Beale Lake, 10 km to the south-southwest of the Nizi property, Meek Lake, 20 km due west of the property and Cry Lake, 20 km to the south-southeast of the property. A small alpine lake lies near the centre of the property and has been referred to as Zinc Lake.

The Nizi property area has a northern continental/alpine climate characterized by snow and sub-zero temperatures from September to May. Due to the high elevations on the property, exploration is best carried out between late June and early September.

CLAIMS & OWNERSHIP

The Nizi project consists of two mineral titles, numbered 515584 (867.58 ha) and 1083872 (1,668.75 ha).

Title number 515584 is registered in the name of Lawrence Edmond Barry, and is subject to an option agreement with Freepath Metals Corp. Title 1083872 is registered in the name of 1155327 B.C. Ltd., and is subject to an option agreement with Freepath Metals Corp.

EXPLORATION HISTORY

Claims on the Nizi property were first staked in 1969 by J. Attenbury. The claims covered a gossanous zone of polymetallic mineralization hosted by quartz veins in "shear" zones.

In 1970, a soil-geochemistry survey (84 samples) and reconnaissance geological mapping were conducted. Anomalous concentrations of lead and zinc were discovered associated with a gossanous area immediately northwest of Zinc Lake and with north-trending topographic lineaments near the northwest end of the property (Zimmerman, 1970).

The property was optioned to Sumac Mines Limited in 1972 who explored for a porphyry-style copper deposit by systematic geological mapping and soil/silt geochemical surveys.

Although several silver-zinc anomalies and a gold anomaly were identified (Rodgers, 1972), the claims were allowed to lapse in 1973.

Regional Resources Limited re-staked the area in 1979. Detailed geological mapping (1:5000 scale) and geochemical surveys were carried out to assess the area's gold and silver potential. Gold, silver, lead, and zinc anomalies identified by Sumac Mines Limited were confirmed and extended and several gold-silver bearing veins were documented (Rowe, 1980).

In 1982, Regional Resources conducted a prospecting and rock sampling program in geochemically anomalous areas and reported that the highest gold values were obtained from massive galena-sphalerite-pyrite vein material (Rowe, 1983).

The claims were allowed to lapse and were re-staked in 1987 by Izumi Exploration Limited (later renamed Gold Giant Minerals Incorporated). A 36.4 km grid was established. Geological prospecting, geochemical and geophysical surveys were undertaken to re-define known anomalies and veins and to locate new ones.

Six main zones of mineralization were identified and named Zones A through F. Precious and base metal mineralization in quartz and quartz carbonate-sulphide veins associated with north- to northwest-trending faults was reported. The widest vein in the B Zone (only partially exposed) returned grades of up to 1.10 g/t (0.032 oz/ton) Au, 3140.9 g/t Ag (91.61 oz/ton) and 6.32% zinc over 0.5 metres (Augsten, 1987).

Additional exploration in 1991 outlined a quartz vein-stockwork system termed the "G Zone" and later the "Discovery Vein". Assay values up to 41.0 g/t (1.196 oz/ton) Au, 764.6 g/t (22.3 oz/ton) Ag over 1.5 metres were obtained for this area (Cavey & Chapman, 1992), (McIntosh & Scott, 1991).

A VLF-EM conductor in this area was interpreted to reflect pyritization associated with the quartz stockwork (Cavey & Chapman, 1992). An airborne geophysical survey was completed in the spring of 1992 (Woolham, 1992) followed by further exploration during the 1992 field season. Soil sampling (650 samples), geological mapping and diamond drilling were carried out. Base and precious metal mineralization associated with minor faults and fractures was reported. The highest assay values were obtained from an area of quartz veining in silicified rhyolite in the Discovery Vein area and the nearby, newly identified "Surprise Vein".

The most significant gold anomaly based on soil geochemistry coincided with the Discovery Vein. Five drill holes, with a total length of 957.38 metres were drilled. Two holes (NZ-92-1, 2) tested the Discovery Vein/Surprise Vein area. The remaining three holes (NZ-92-3, 4,5) tested the H Zone, Grizzly Ridge Vein/Discovery Vein and Gully A Zone, respectively.

Three additional holes (NZ-92-6, 7, 8) were drilled in the Discovery Vein area by Gold Giant Minerals Incorporated. Drilling indicated the continuity of gold-bearing structures. High gold assays were reported for smokey blue/grey quartz veins throughout the cored intervals, for a quartz-flooded, grey to black rhyolite cut by veins of quartz + carbonate + sulphides and for apparent fault zones within and near the contacts of the rhyolite. In general, gold assays were lower than surface assays (Bond, 1993) and the claims were allowed to lapse.

In 1994, claims were re-staked in the Nizi area by Lawrence Barry of Hunter Explorations. The property was optioned by Oro Grande Resources Inc. in 1995 to earn a 100% interest in the property. Madrona Mining Limited entered into an agreement with Oro Grande Resources in July 1996 with an option to earn up to 60% interest in the property.

In September 1996, six diamond drill holes with a total length of 3022 feet (921.1 metres) were drilled by Madrona Mining in joint venture with Oro Grande Resources. Five holes were drilled in the vicinity of the Discovery and Surprise Veins. One hole was drilled to test the southeastern extension of the Zinc Lake Zone. Zone E of (Augsten, 1987) and (Bond, 1993).

Significant gold mineralization was encountered in holes NZ-96-9, -10 and -12. Base-metal mineralization (sphalerite and galena) was encountered in holes NZ-96-10, -12 and -13 in what was reported to be a sub-vertical (75 degrees-85 degrees dip), northwest-striking zone of fault breccia. The breccia contained layered and massive sphalerite-galena-rich clasts. The clasts were interpreted by Day (1996) to reflect volcanogenic massive sulphide mineralization at depth, the clasts having been torn away and incorporated in the breccia by faulting.

In July 1997 the Nizi property was re-mapped for Madrona Mining Limited at a scale of 1:20,000 by Heather Plint assisted by Alli Marshall. Mineralized areas (Zinc Lake Zone, Discovery Zone and Gully A Zone) were mapped in detail. Drill core from the 1996 exploration program was re-logged with the aim of identifying a volcanic stratigraphy and lithologic and structural controls on mineralization.

In September 1997, Madrona Mining Ltd. completed a total of 914.73 metres (3001.07 feet) of diamond drilling in five drill holes on the Nizi property. A total of four holes were drilled from two sites to test the northern and southern extents of the Discovery/Surprise Vein mineralization. One hole was drilled on Telephone Hill to test a rhyolite flow dome for precious metal mineralization.

Type 1 mineralization was encountered in all four holes in the Discovery/Surprise Vein area, although no significant assays were obtained for samples in drill hole NZ-97-18. Epithermal carbonate-quartz-chert-sulphide veins and breccias (Type 2 mineralization) were encountered in all four drill holes. NZ-97-15 assayed up to 1.43 g/t gold over a true width of 1.0 metre. Individual samples assayed up to 1.96 g/t gold. Type 2 mineralization is slightly anomalous in gold and silver. One sample (#261116) returned values of 0.298 g/t gold and 29.0 g/t Ag. NZ-97-16 assayed up to 3.98 g/t Au and 11.51g/t silver over a true width of 1.71 metres. A 1.5 metre-long sample of Type 1

mineralization, overprinted by brittle faulting at the western contact of the rhyolite returned values of 5.08 g/t gold and 1.55 g/t silver. A 1.38 metre-long sample of Type 1 mineralization in a porphyritic flow returned values of 8.32 g/t Au and 24.6 g/t silver. Type 2 mineralization in this drill hole was not anomalous in gold or silver.

In drillhole NZ-97-17, Type 1 mineralization was encountered as thin veinlets and as a vein-breccia but did not assay significant gold. Type 2 mineralization was anomalous in silver and gold averaging 0.384 g/t gold and 11.11 g/t silver over a 2.62 metre-long interval.

NZ-97-18 encountered Type 1 mineralization hosted by silicified and bleached rhyolite and porphyritic flows. A one metre-long interval of such mineralization returned values up to 7.0 g/t gold and 181.0 g/t silver. A 2.23 metre-long interval of Type 2 mineralization was encountered at 130.3 to 132.53 metres and thin veins of Type 2 mineralization were intersected throughout the hole. Type 2 mineralization is anomalous in silver and in one sample, anomalous in gold (sample #261370) assayed 1.09 g/t gold and 90.40 g/t silver.

Geological work done by Madrona was thorough, and several significant observations were made through their detailed work. Correlation of surface and subsurface data by Madrona in 1997 indicates that the silicified porphyritic rhyolite is a northerly striking, steeply dipping to vertical unit. This observation, the distinctive chemistry of the silicified porphyritic rhyolite, the presence of euhedral to subhedral K-feldspar and minor quartz phenocrysts in an extremely fine-grained siliceous matrix and the absence of flow foliation in the rhyolite suggest that it is a subvolcanic intrusion.

The drill core and surface data indicated that the rhyolitic subvolcanic intrusion either pinches out towards the south or may be deflected into a more east-west strike. The minor amount of significant gold assays in drill hole NZ-97-16 relative to NZ-97-18, suggested that the mineralization in the upper 150 metres of the sequence is tapering out towards the south.

Drill hole NZ-97-17 intersected a minor amount of significant gold mineralization compared to hole NZ-97-15. This could reflect a decrease in mineralization north of the Discovery Vein. However, Type 1 mineralization was intersected in Gold Giant Minerals' drill hole NZ-92-3 that was collared 240 metres north of the Discovery Vein.

In drill hole NZ-97-15, amygdules and feldspar phenocrysts in volcanic flow are aligned parallel to the rhyolite contact although they show no alignment throughout the rest of the volcanic flow. This observation was thought to suggest that the hydrothermal alteration may be masking syn-volcanic faults at the rhyolite contacts.

One geological, wildcat hole was drilled by Madrona on Telephone Hill to test the rhyolite flow dome for mineralization. The drilling confirmed surface mapping that indicated that the flow domes in this area are underlain by a thick sequence (up to 170 metres) of gently dipping volcanic tuff. Rhyolite was not intersected. A 9.0 metre-long interval of felsic to intermediate lithic-crystal lapilli tuff cut by Type 1 mineralization stockwork, minor pyrite stringers and minor Type 2 mineralization in veinlets assayed 7.1 g/t silver. A 6.59 metre-long interval of felsic to intermediate lithic-crystal lapilli-block tuff cut by chert stockwork and Type 2 mineralization assayed 11.34 g/t silver. The highest silver assay in this interval is 23.0 g/t for sample #261453 that is dominated by Type 2 mineralization.

In 2007, Romios Gold Resources mapped and evaluated the known showings and defined potential drill targets for future work on the Nizi property. A program consisting of 1:5000-scale geological mapping, prospecting and rock sampling was conducted. In total, 43 rock samples were taken as well as 26 samples were subjected to ASD spectrometer petrographic analysis for clay and alteration mineralogy.

REGIONAL GEOLOGY & MINERALIZATION

Mapping by the Geological Survey of Canada (Gabrielse, et al., 1979) placed the rocks of the Nizi property into the Sylvester Allochthon. The Sylvester Allochthon is composed of three thrust-bounded assemblages. The structurally lowest assemblage is the Slide Mountain Terrane (SMT), interpreted to be remnants of a Mississippian to Permian ocean basin or marginal basin that separated ancient North America (now the Cassiar Terrane, in part) from terranes to the west.

The SMT is overlain along a major thrust by Mississippian to Permian island arc rocks of the Harper Ranch Terrane (Nelson, 1993) in turn overlain by the Rapid River Tectonite (RRT). The RRT is exposed in the southeastern portion of the Sylvester Allochthon (Harms, 1990) and (Harms, 1993). It is an assemblage of amphibolite grade, intercalated mylonitic tectonites and intrusive rocks. Metamorphism, mylonitization and quartz diorite intrusion in the RRT are dated by a synkinematic quartz diorite at Late Devonian to Early Mississippian (362 to 350 Ma) (Gabrielse, et al., 1993). The regional affinity of the RRT is unknown (Harms, 1990) but it may be part of the Yukon-Tanana Terrane.

Terranes outboard of the Sylvester Allochthon and SMT include the Cache Creek, Stikine, Quesnellia and Yukon-Tanana Terranes. The Cache Creek Terrane is interpreted to represent early Mississippian to Permian, oceanic basement upon which developed island arcs and related intra-arc or fore-arc sediments (Gabrielse, 1991).

The Cache Creek and SMT are largely the same age and composed of similar rock types. They are distinguished by the presence of Permian fossils (called “Tethyan faunas”) in the Cache Creek Terrane and the absence of coeval faunas in the SMT (e.g. (Mortensen, 1992)). The Tethyan faunas are similar to those in Japan, China, Indonesia and the Himalayan region and very different from coeval fossils in North America, indicating that the Cache Creek Terrane is a far-traveled terrane (Monger & Ross, 1971).

The Stikine Terrane is an island-arc terrane, composed of a variety of rock types, ranging in age from Mississippian to Early Jurassic. The Quesnellia Terrane is similar to the Stikine Terrane and interpreted to have formed in a Late Triassic to Middle Jurassic island arc and intra-arc setting (Gabrielse, 1991).

The Yukon-Tanana Terrane (YTT) consists of polydeformed and metamorphosed rocks derived from the pre-Devonian to Upper Triassic sedimentary, volcanic and plutonic rocks. Much of the SMT was subducted in Permian to Triassic time, as outboard terranes collided with North America. As the ocean basin closed, klippen of the SMT, Harper Ranch and RRT were obducted eastward over Proterozoic to Devono-Mississippian rocks of the North American continental margin and locally, westward over outboard terranes (e.g. (Plint & Gordon, 1997) and (Price, 1986)).

Numerous Cretaceous to Tertiary, northwest-trending, dextral strike-slip faults dissect the Canadian Cordillera. These faults are attributed to Cretaceous and younger, oblique collision of far-traveled terranes with the western margin of North America. In the northern Cordillera, the strike-slip faults have modified terrane boundaries (e.g. (Gabrielse, 1985), (Gabrielse, 1991), (Wheeler & McFeely, 1991)). Basaltic to rhyolitic volcanism along these strike-slip faults is common (Christie, et al., 1992) , (Jackson, et al., 1986).

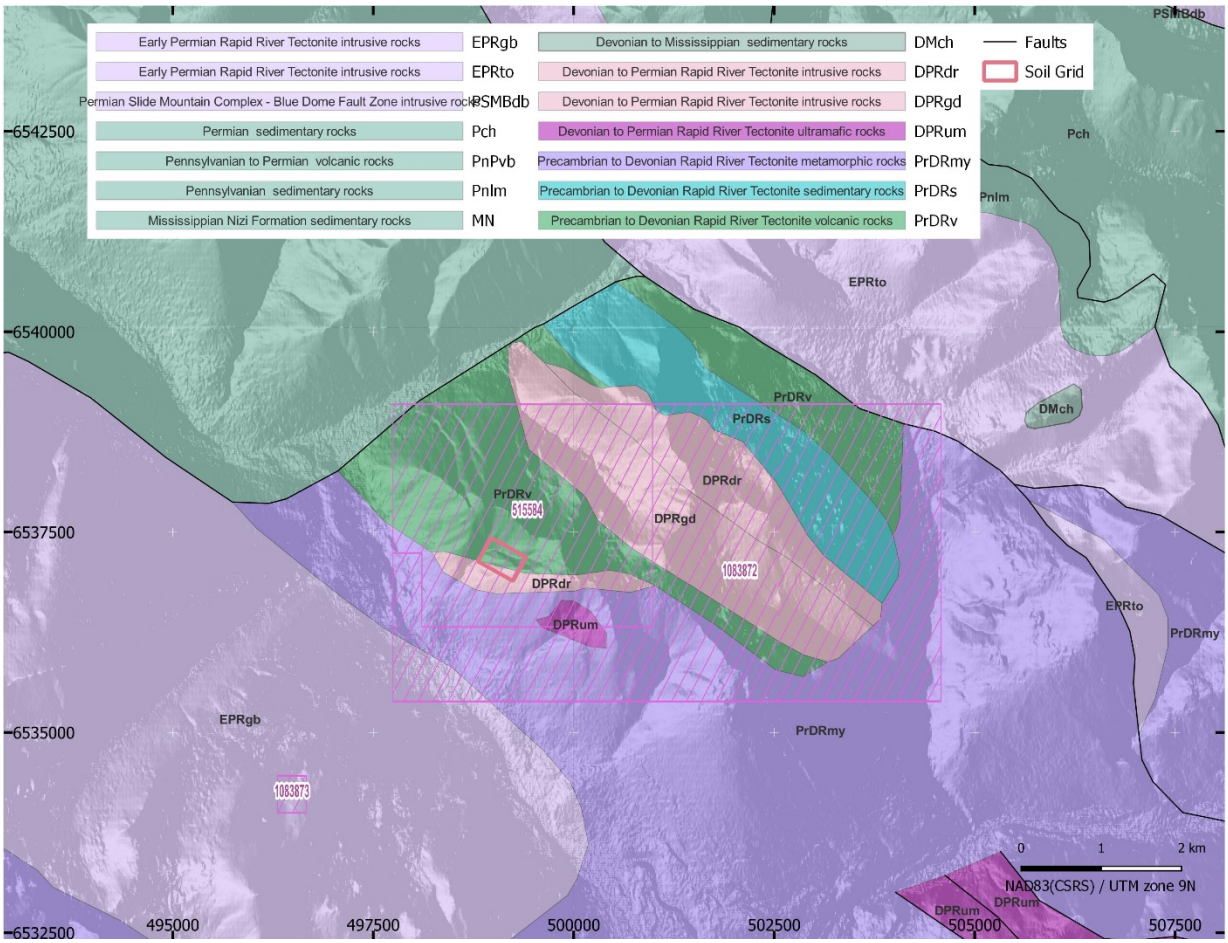

Figure 3: Regional bedrock map of Nizi area and location of soil sampling grid

The Nizi property lies in a region of high potential for economic mineralization. A wide variety of base and precious metal occurrences and deposits are present in the region. To the north, within 50 to 75 km of the Nizi property are numerous base and precious metal and industrial mineral deposits and occurrences in a region referred to as the Midway-Cassiar area. Seven mineralizing episodes, Devonian to Tertiary in age, are recognized in the Midway-Cassiar area (Nelson, 1993):

1. Exhalite deposits in the Devono-Mississippian Earn Group and within units of the SMT generated by Devono-Mississippian extensional tectonics;

2. Rhodonite, of probable exhalative origin in Pennsylvanian-Permian chert of the SMT;

3. Syngenetic chromite and trace platinum mineralization in the Zus Mountain-Blue River and Cassiar ultramafic bodies of the SMT;

4. Early mid-Cretaceous, mesothermal gold-quartz veins hosted by basalt of SMT (e.g. Erickson mine, Taurus Vein, Hopeful Vein) and asbestos fibres in extensional veins (e.g. Cassiar and McDame mines) that are interpreted to have been produced by a cryptic approximately 130 Ma intrusive body (Sketchley, et al., 1986);

5. Mid-Cretaceous skarns and silver-lead-zinc veins and replacement bodies related to the intrusion of the Cassiar Batholith (ca. 100 Ma);

6. Molybdenum-copper skarns and porphyries, and distal silver-lead-zinc replacement bodies (e.g. Midway deposit) formed by a 70 Ma intrusive event;

7. Porphyry mineralization, skarns and silver-lead-zinc veins related to the Eocene Mount Haskin and Mount Reed stocks.

Important ongoing exploration efforts in the area are diverse, and the area is undergoing a resurgence of interest and activity over the last few years. The largest players in current exploration are outlined below:

1) The Western Keltic Mines Kutcho Project, 100km east of Dease lake is slated for production targeted for 2010. A prefeasibility study of this poly-metallic Volcanigentic Massive Sulphide deposit proved a 17.6 million tonne reserve of 1.17 % Copper, 2.36% Zinc, 27.45% Silver and 0.34 g/tonne Gold.

2) The Imperial Metals Red Chris copper porphyry deposit is located 80km south of Dease Lake. A 2004 feasibility study put reserves at 276 million tonnes with .349% copper and .266 g/tonne gold. At 30,000 tonnes/day, this would create a 25 year mine life for the project.

3) The Canadian Gold hunters GJ (Kinaskan) Copper-Gold porphyry project 75km south of Dease Lake. Inferred resources total 71.22 million tonnes grading .392% copper, .398 grams/tonne gold and 2.2 grams/tonne silver.

4) The Table Mountain Gold Mine district, in the vicinity ofthe Cusac Mine, a high-grade underground gold mining operation located on the Cassiar-Stewart Highway. Total gold production to date from the Cassiar area is about 423,500 oz (13,172 kg) of gold. Production revenues commence in the mid 1980s with Total Energold mining, who had a 300 ton per day mill. In 1993, Cusac restarted gold production, producing 60,000 ounces of gold between 1993 and 1997. The mine ceased producing when gold prices dropped dramatically in 1997. Gold recommenced in December 2006. Table Mountain processing and support facilities consist of a 300 ton-per-day operation, centrally located in the camp adjacent to McDame Lake and Highway 37.

PROPERTY GEOLOGY & MINERALIZATION

The geology of the Nizi property is divided into 4 major map units (in order of oldest to youngest):

1. A metamorphic sequence of metasedimentary, metavolcanic and metaplutonic schist and orthogneiss;

2. An intrusive unit of fine- to coarse-grained, non-foliated granodiorite, quartz diorite and diorite;

3. A sequence of subaerial, felsic to mafic volcanic flows and pyroclastic rocks (hereafter the "Nizi volcanic sequence"); and,

4. Kaolinitized orthoclase-quartz- (biotite) porphyry.

The map units are described in detail by (Plint & Panteleyev, 1997) and (Plint, et al., 1998). Unit 1 is correlated with the Rapid River Tectonite and Unit 2 with the Slide Mountain Terrane. The Nizi volcanic sequence is not part of the Slide Mountain Terrane and its regional correlation unclear. It consists mainly of intermediate to mafic amygdaloidal, porphyritic flows and lithic-crystal tuffs and lesser rhyolitic and dacitic volcanic flows, welded tuff and subvolcanic porphyritic dykes.

Rhyolitic and dacitic flows form a flow dome(s) in the vicinity of Telephone Hill near the centre of the map area. A rhyolitic dyke is exposed over a strike length of 400 metres in the Gully Zone area. Porphyritic, rhyolitic rocks are exposed and partially host mineralization in the Discovery Vein area. The absolute age of the Nizi volcanic sequence is unknown although it must be younger than mid-Permian diorite of SMT that it intrudes (Plint & Panteleyev, 1997).

The Nizi volcanic sequence lies within a south-easterly tapering, fault-bounded structure. The north-eastern boundary of the sequence is now a northwest trending fault with dominantly dextral strike-slip motion. The south-eastern boundary is, in part, a west- to northwest-trending fault with uncertain displacement. Based on the west-northwesterly trend of the contact, fault motion probably has been dominated by reverse slip and dextral strike-slip. (Plint, et al., 1998) and (Plint & Panteleyev, 1997).

Tectonic structures in the Nizi volcanic sequence consist of joints, fracture cleavage and small scale faults. Many of these structures can be related to strike-slip faulting although documentation of displacement is hindered by the paucity of marker beds. In mineralized areas, north, northwest and northeaststriking, steeply dipping to vertical joints and fracture cleavage are well developed (Plint, et al., 1998). Resistivity data reveals that northwest-striking, dextral fault zones and northeast-striking and north-striking fractures or faults, dissect the Nizi property and surrounding area (McGowan, 1997)
.
Madrona (Day, 1996) completed a thorough study of the type and style of mineralization seen in both the drillcore and in the geological mapping of the mineralized zones. Their conclusions are summarized below:

There are 6 main mineralized areas known on the Nizi property: Zinc Lake Zone (E Zone), Discovery Vein/Surprise Vein, Grizzly Ridge Vein, H Zone, Gully A Zone and B Zone. In addition,

the Telephone Hill Zone was recognized as an area of interest on the basis of 1997 mapping and assays reported by Gold Giant (Bond, 1993)

Mineralization of economic interest on the Nizi property occurs in vein-stockwork systems with associated hydrothermal brecciation. It is divisible into (1) gold silver-quartz-dominated and (2) carbonate-quartz-pyrite-sphalerite-galena dominated mineralization.

Type (1): Gold-Silver-Quartz-dominated Mineralization

Gold-silver-bearing vein-stockworks consist of translucent to opaque, microcrystalline to very fine-grained, white to grey quartz, carbon, finely disseminated pyrite or veinlets of pyrite, locally white subhedral to euhedral barite and minor dolomite and possibly plagioclase (e.g. Zinc Lake Zone, Discovery Vein/Surprise Vein, Hill Zone).

Fine disseminations of sphalerite, galena, acanthite, tetrahedrite and rare chalcopyrite are present in the vein-stockworks. Gold and silver are present as very fine grains of electrum included in or intergrown with the sulphides and sulfosalts (Pwell, 1997). The pyrite appears to be late in the crystallization sequence because it is typically euhedral to subhedral and overprints contacts between other sulphides and sulfosalts.

Barite precipitated late in the gold mineralization sequence, locally as replacements along quartz grain boundaries in the Type 1 mineralization or as veinlets that cut the Type 1 mineralization.

Type (2): Carbonate-Quartz- Sulphide-dominated Mineralization

Carbonate – quartz – pyrite - sphalerite – galena veins, stockworks and breccias are present in the Gully Zone, B Zone and H Zone and in drill core in the Discovery Vein, Telephone Hill and Zinc Lake Zone areas. Carbonate minerals include rhodochrosite, dolomite and probably ankerite. Minor barite is present locally.

The microcrystalline to finely crystalline quartz in these veins is commonly opaque. Generally, the veins and breccias are anomalous in silver and locally anomalous in gold. The veins exhibit colloform banding, crustification and cockscomb textures and multistage, hydrothermal breccia textures. In drill core, the mineralization has alteration halos of bleached, beige or yellowish pale green coloured, soft argillaceous material and/or chlorite.

2021 EXPLORATION PROGRAM

A four-person crew was mobilized to the site by helicopter between September 10 and 14, 2021. The crew utilized a fly camp as a base to conduct soil sampling on the south side of a roughly east-west trending ridge, as well ridge-and-spur rock sampling along the ridge. The sampling area is shown in Figure 3 and **Error! Reference source not found.**.

A total of 101 soil samples were collected on a 50 x 50-meter grid shown in Figure 5. Soil samples were collected with a hand auger, with sample material taken from the 'B' horizon of the soil profile. Soils observed during the sampling ranged from light to dark brown in colour, with textures ranging from sandy to clay loam.

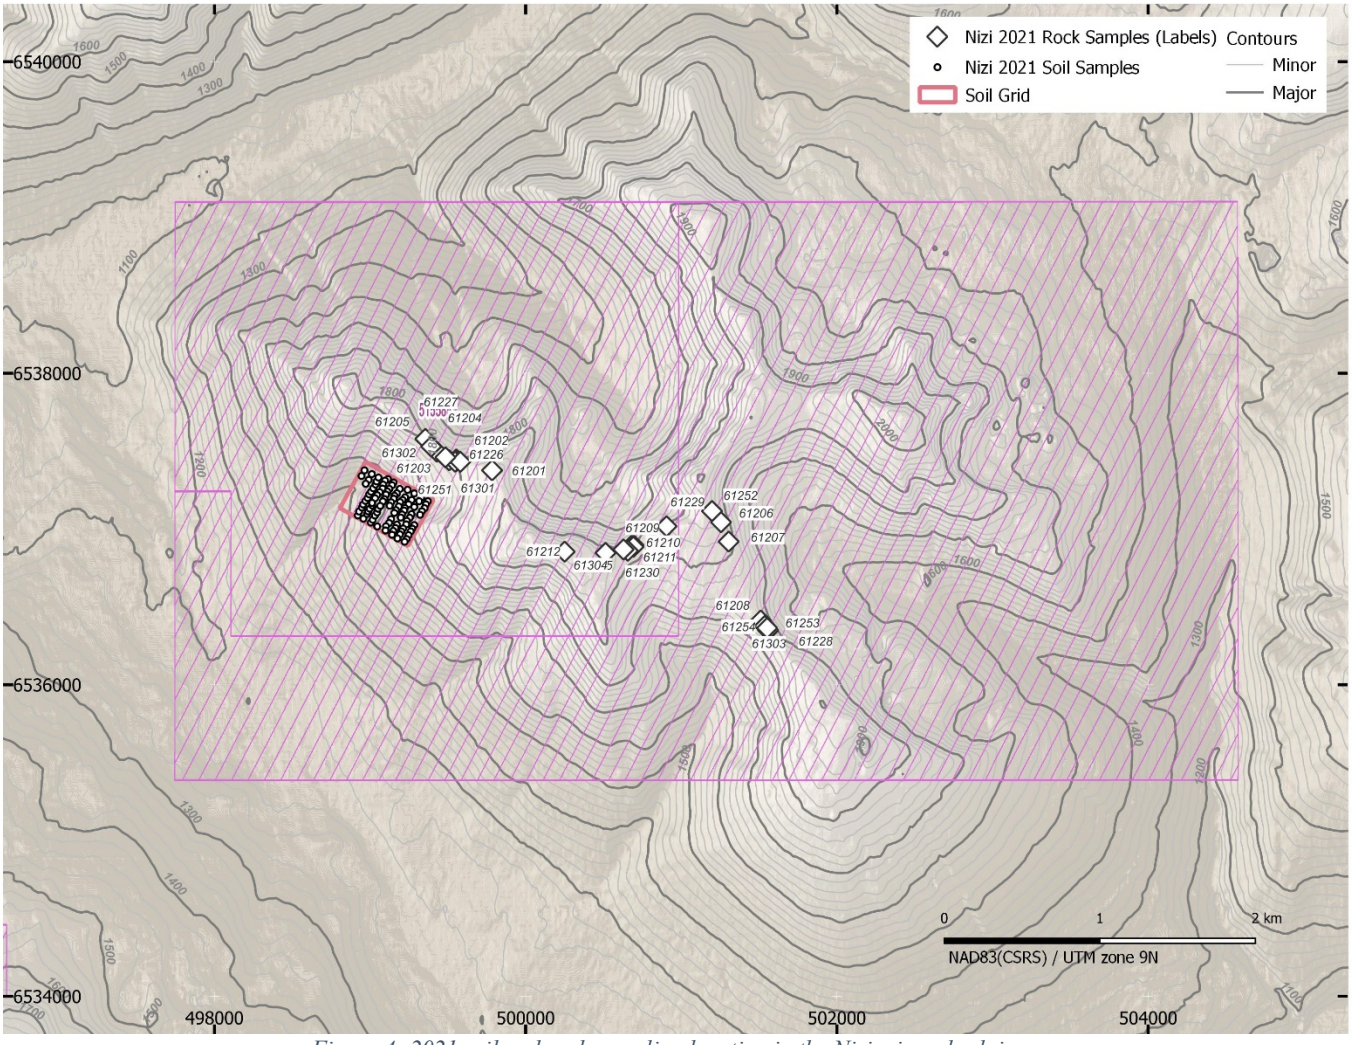

Figure 4: 2021 soil and rock sampling location in the Nizi minerals claims

After removal from the auger, soil samples were hand sorted to remove gravels and pebbles wherever possible. Samples were placed in Kraft envelopes, which were tagged for identification. GPS locations of samples were taken. Individual sample bags were placed in rice sacks for shipment to ALS Laboratories in Kamloops for sample preparation were they were

dried at <60 degrees C and sieved to -180 micron (80 mesh). Prepped samples were analyzed at ALS Laboratories in Vancouver using the AuME-ST44 package where a 50 gram sample is analyzed for 53 elements. Sample descriptions are included in Appendix 1, with assay results in Appendix 2.

A total of 26 rock samples were also collected, by hand from outcrop, subcrop or boulders. Samples were placed in plastic bags, which were tagged for identification. GPS locations of samples were taken. Individual sample bags were placed in rice sacks for shipment to ALS Laboratories in Kamloops for sample preparation were they were crushed to 70% passing 2 millimeters, with a 250 gram split then taken and crushed to better than 85% passing 75 microns. Prepped samples were analyzed at ALS Laboratories in Vancouver using the AuME-ST44 package where a 50 gram sample is analyzed for 53 elements. Sample descriptions are included in Appendix 3 and assay results in APPENDIX 4:.

RESULTS

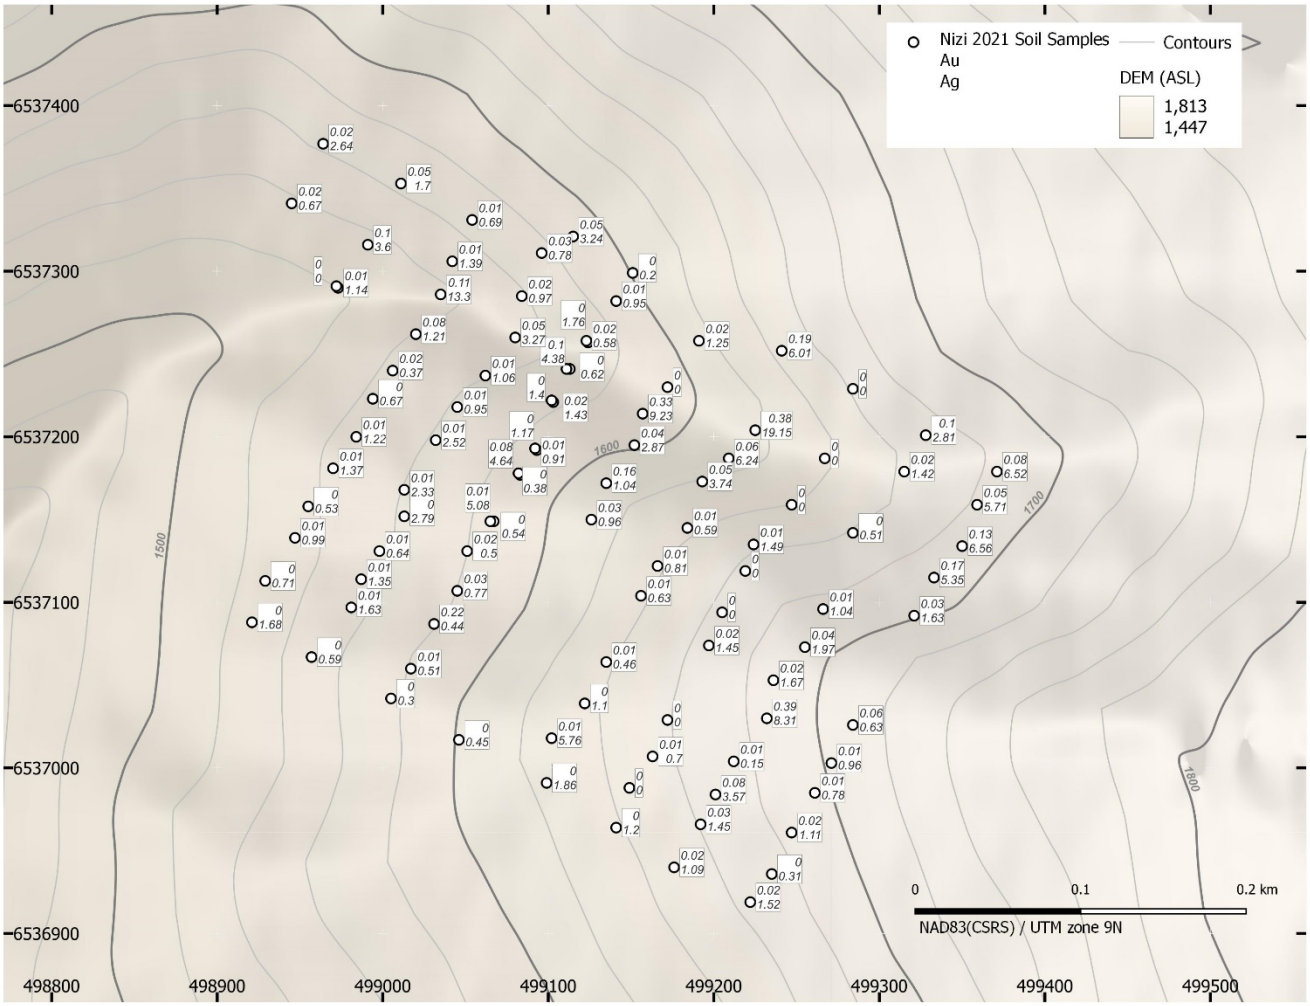

Figure 5: Au and Ag soil sample results of 2021 sampling programme.

The highest Au value measured in the soil sampling was 0.39ppm Au with 8.31 ppm Ag. The next highest gold sample, at 0.38ppm Au, contained the highest Ag value of 19.15ppm. 70% of the analyzed soil samples had values of <0.02ppm Au, and 56% of samples were below 0.1ppm Ag.

Correlation coefficients between Au and other elements shows that high Au is correlative with anomalous Ag (0.75 correlation coefficient), As (0.81), Pb (0.7), Zn (0.63) and Sb (0.65) amongst others. Ag shows similar correlation coefficients with the same elements. Negative correlation between target metals and immobile metals such as Ti and Zr suggests that mineralization is not limited to a specific rock type, consistent with previous work that identified 2 primary forms of vein hosted mineralization. The association with Pb, Zn and other base metals matches the previous descriptions of mineralization styles (minor galena and sphalerite were noted in both type 1 and type 2, see page 14).

The new sampling extends previously identified anomalies by Solomon Resources, 2009 (**Error! Reference source not found.**). 5 Samples collected in 2021 were planned to duplicate previous work to test repeatability with prior work. Results are very similar between the datasets highlighting the excellent quality of both (for instance 0.171ppm vs 0.13 ppm, Figure 6).

The distribution of anomalous Au values in the sampling area suggests some down-slope dispersion in a NW direction. This is likely considering the dramatic topography in the Nizi claim area (Figure 7). The largest identified anomaly in thr 2021 sampling is currently open up-slope to the NE and will require additional work in the future.

According to the regional geological map (Figure 3) and more detailed work by Solomon Resources (**Error! Reference source not found.**) the soil grid covers a major lithological contact between intermediate to mafic volcanics (the Nizi Volcanic sequence) and intrusive granodiorites – diorites. Except for the southernmost Au anomaly sampled in 2021, Au appears to be limited to the volcanic sequence. Additional mapping is required to determine with accuracy.

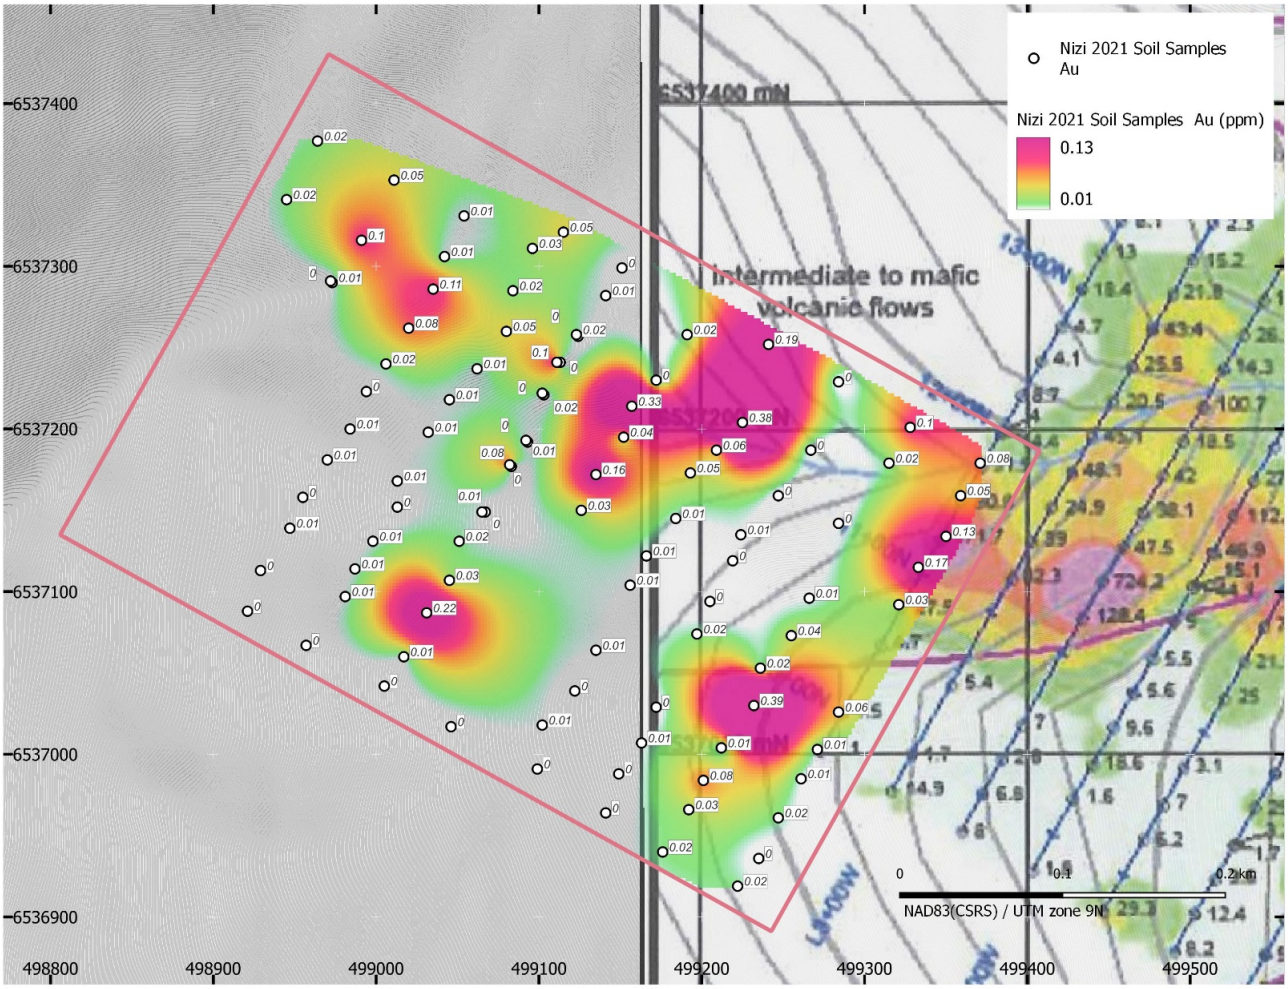

Figure 6: Gridded 2021 Au sampling results and historic Au results map (background, Solomon Resources 2009). Colour scales have been matched between the datasets.

Figure 7: Photograph looking NE of sampling teams working in the Nizi claims around Zinc Lake (pictured).

Of the 26 rock samples collected in 2021, 1 sample (61209) assayed >150ppm Ag, 9.71ppm Au and 5.21% Zn. The sample was taken from an outcrop of gossan that has been mapped in the past by Gold Fields, Sullivan Rodgers and The Logan Joint Venture. The relatively high Au, Ag and Zn grade would suggest that this sample fits in the "Type 1" style of mineralisation described on page 14. The 5.21% Zn in sample 61209 is the only economic grade of base metal mineralisation noted in the project area. Sample 61211 was taken 20m away in the same gossan and a returned the second highest Au value at 0.355ppm and the highest As value measured at 4270ppm As. Previous soil sampling in this area has been limited and will require further work.

3 other samples assayed over 0.2ppm Au (61204, 61205, 61302) and were collected along a ridge within 200m of each other near to the historic 'Surprise Vein' area. Each sample was noted as gossanous. Previous mapping has not identified gossan in this area before. These samples are also 350m directly upslope (NE) of the new Au soil anomaly identified (Figure 6). More work is required to determine the extent of the underlying gossan and its downslope dispersion.

STATEMENT OF QUALIFICATIONS

I, David W. Forest, of 2788 Prince Edward Street, Vancouver, BC V5T 0C8, hereby certify:

1. I am a self-employed consulting geologist with greater than 20 years experience in the mining and exploration industry.

2. I am a graduate of the University of Alberta (1999) with an Honours Bachelor of Science in Geology.

3. I have served in management roles with mining and exploration companies including Chief Operating Officer and Vice-President of Exploration.

4. I have direct experience in the geology of porphyry copper-gold deposits of the type targeted by this project.

5. I am directly involved with this project as I initiated the work on claims and have an ownership position in the company holding the claims, and therefore have the potential to financially gain.

6. I believe this report to be correct and based on factual information.

Dated this 10 day of 2022.

STATEMENT OF COSTS

See attached.

Exploration Work type	Comment	Days			Totals
Personnel (Name)* / Positio	**Field Days (list actual days)**	**Days**	**Rate**	**Subtotal***	
Steve Gillanders	Sept 8 to 16, 2021	7	$750.00	$5,250.00	
Curtis Rensby	Sept 8 to 16, 2021	7	$480.00	$3,360.00	
Cody Prince	Sept 8 to 16, 2021	7	$480.00	$3,360.00	
Alain Laurencelle	Sept 8 to 16, 2021	7	$480.00	$3,360.00

CERTIFICATE KL21262184

Project: High Road

This report is for 101 samples of Soil submitted to our lab in Kamloops, BC, Canada on 29-SEP-2021.

The following have access to data associated with this certificate:

DAVID FOREST

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
DISP-01	Disposal of all sample fractions
SCR-41	Screen to -180um and save both

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
AuME-ST44	50g Super Trace Au + Multi Element PKG	

Appendix 2: Soil Sample Analytical Results

This is the Final Report and supersedes any preliminary report with this certificate number.Results apply to samples as submitted.All pages of this report have been checked and approved for release.
***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE OF ANALYSIS KL21262184

CERTIFICATE COMMENTS

ANALYTICAL COMMENTS

Applies to Method: NSS is non-sufficient sample.
ALL METHODS

LABORATORY ADDRESSES

Applies to Method: Processed at ALS Kamloops located at 2953 Shuswap Drive, Kamloops, BC, Canada.
DISP-01 LOG-22 SCR-41 WEI-21

Applies to Method: Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.
AuME-ST44

Description

Gossan, silicified rock with rusty qz veining
Felsic volcanic, gossan, silicified, fine-grained disseminated sulfides 5%
Fine-grained felsic volcanic, gossan, silicified, fine-grained disseminated py 10%
Fine-grained medium grey mafic volcanic with qz veining, gossan, silicified, fine to medium-grained py in and adjacent to veins, 5%
Fine-grained grey mafic volcanic, gossan, epidote, fine-grained py disseminated and stringers 5%
Silicified mafic volcanic, gossan, fine-grained py disseminated and stringers, 2%
Sub-rounded schist float, gossan and rusty, chlorite altered, py and silver-colored sulphide disseminated and stringers 2%
Very gossanous, fine-grained mafic, silicified, qz veinlets (strike 126, dip 70)
Gossan vein, qz-cb, silicified, vein of sulphides, unidentified black mineral band (translucent with green sheen)
qz vein, sulphide bands, py and cp disseminated and in patches 10%
Gossan, chlorite altered mafic volcanic, silicified, vessicles on weathered surface, fine-grained py in bands
Gossan, silicified mafic volcanic, qz, fine-grained py disseminated 2%
Fine-grained felsic volcanic, silicified, v. fine-grained py disseminated 2%
Silicified dark grey mafic volcanic, gossan, fine-medium grained py and cp disseminated 2%
Grey to black schist with quartz veining containing sulphides and some gossan
Grey intermediate volcanic with some quartz veining containing pyrite
Grey felsic volcanic with quartz veining and sulphides, minor bornite staining in qz
Rusty grey felsic volcanic, minor sulphides with rusty vein
Grey mafic volcanic with with 10mm wide quartz vein, medium-grained py patches in vein <1%
Silicified grey mafic volcanic with quartz vein, minor sulphides and rust
Fine-grained grey mafic volcanic with quartz vein, minor py and rust in mafic
Grey fine-grained mafic volcanic with qz vein, epidote staining and minor sulphides
Very gossanous, light grey felsic volcanic, fine-medium grained py disseminated and in patches 5%
Very gossanous, light grey, pyrite, some quartz, fine grain
Gossanous, felsic volcanic, pyrite, quartz vein (strike 300, dip 60)
Very gossanous, felsic volcanic, minor pyrite

CERTIFICATE KL21262187

Project: High Road

This report is for 26 samples of Rock submitted to our lab in Kamloops, BC, Canada on 29-SEP-2021.

The following have access to data associated with this certificate:

DAVID FOREST

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
DISP-01	Disposal of all sample fractions
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize up to 250g 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Ag-OG46	Ore Grade Ag - Aqua Regia	
ME-OG46	Ore Grade Elements - AquaRegia	ICP-AES
Au-AROR44	Au AR Overrange - 50g	
Zn-OG46	Ore Grade Zn - Aqua Regia	
AuME-ST44	50g Super Trace Au + Multi Element PKG	

Appendix 4: Rock Sample Analytical Results

This is the Final Report and supersedes any preliminary report with this certificate number.Results apply to samples as submitted.All pages of this report have been checked and approved for release.
***** See Appendix Page for comments regarding this certificate *****

CERTIFICATE OF ANALYSIS KL21262187

CERTIFICATE COMMENTS

LABORATORY ADDRESSES

Processed at ALS Kamloops located at 2953 Shuswap Drive, Kamloops, BC, Canada.

Applies to Method:	CRU-31	CRU-QC	DISP-01	LOG-22
	PUL-31	PUL-QC	SPL-21	WEI-21

Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.

Applies to Method:	Ag-OG46	Au-AROR44	AuME-ST44	ME-OG46
	Zn-OG46
