# LIST OF FIGURES

# 1.0 INTRODUCTION

The following report presents results from (i) 2021 rock prospecting and (ii) multispectral satellite alteration mineral mapping conducted across the Toro property which is located in north eastern British Columbia (**Fig. 1**). The claims are currently owned by High Range Exploration and Fabled Copper Corp. The Toro property comprises 11 mineral tenures covering approximately 1392 ha (**Fig. 2**).

The Toro property is located within the Muskwa Anticlinorium, a Proterozoic assemblage of sedimentary rocks considered to be temporally related to parts of the Wernecke Supergroup in the Yukon territory, which host significant iron-oxide copper-gold (IOCG) mineralization (Carne, 2006). Copper was originally discovered in the region during the construction of the Alaska Highway in the 1940's. Widespread exploration took place from 1950 to the early 1970s and resulted in the discovery and production of both the Magnum and Davis-Keays deposits which both saw intermittent mining until 1974.

The key objectives of the 2021 work program were to:

i) Carry out fieldwork and prospecting at accessible locations across the Toro claims in order to verify historical assay results and assess mineralization styles.

ii) Conduct alteration mineral mapping and targeting using Visible Near Infrared (VNIR), Shortwave Infrared (SWIR) and Thermal Infrared (TIR) Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) multispectral satellite data.

Field work was carried out by a four-person team consisting of Fabled Copper Corp. staff and Geomantia Consulting was contracted by Fabled Copper Corp. to carry remote sensing data processing, analysis and final report writing. Geomantia Consulting was also on site during the 2021 Fabled Copper Field campaign. A Statement of Qualifications appears in Appendix I and the Statements of Costs appear in Appendix II. Analytical certificates are presented in Appendix III. Field prospecting information is presented in Appendix IV. All maps are drafted in the NAD83 (CSRS) datum and projected to UTM zone 10.

## 2.0 PROPERTY, LOCATION AND ACCESS

The Toro property is located approximately 530 km NNW of Prince George, 155 km WSW of Fort Nelson, B.C. and 53 km S of Toad River (**Fig. 1**). The claim area is centered at latitude 58°21'37.57" N, and longitude 125°11'42.98" W within the Northern Canadian Rocky Mountain Ecoregion 2, specifically in the eastern Muskwa Ecosection. The area is flanked by the Northern Rocky Mountain Park to the east, Muncho Lake Park to the north, Dune Za Keyih Park to the west and Kwadacha Wilderness Park to the south (Carne 2006). The eleven mineral tenures of the Toro property are located in the Liard Mining Division on NTS map sheet 94K. Claim data are listed in **Table 1** while the locations of the individual tenures are shown on **Figure 2**.

**Table 1:** Toro Property Claim Data Summary

Elevation ranges from 1120 m to 2560 m above mean sea level. Access is by helicopter from Toad River and a former haulage road extends from MacDonald Creek into the property however the bridges have been removed (Carne, 2006). During 2021 field activities attention was paid to accommodating outfitter's schedules and helicopter flight paths respected existing legislation pertaining to shared land use.

## 3.0 PHYSIOGRAPHY & VEGETATION

The following outline is summarized from Carne (2005) and Campbell (2016). The Toro property is characterized by significant topographic relief with pronounced peaks, jagged ridges and wide U-shaped valleys occupied by braided rivers. Lower slopes are covered by open scree grading into moderate to dense growths of spruce trees on valley bottoms. Both the Alpine Tundra and the Spruce-Willow-Birch climatic zones are represented on the Muskwa property. Tree line is at approximately 1400 m. Local glaciation has produced numerous moraines and has deposited variable thicknesses of till up to an elevation of about 1500 m. A number of glaciers still exist at high elevations particularly in north and east facing cirques. Creeks draining the property flow into the Racing River, which is a tributary of the Liard River.

This area is protected from moist Pacific air moving over the mountains to the west, however low-pressure storms in Alberta pushing moisture eastward over the Alberta Plateaus to the east can result in extreme rain events. In the winter and early spring, dense, cold Arctic air can invade this area by coming down the Interior Plains to the north.

## 4.0 PREVIOUS WORK

The following summary of work history in the project area is taken from Carne (2006). The discovery of copper mineralization in the Muskwa Anticlinorium in the early 1960's was followed by intense regional exploration focussed on the high grade copper bearing quartz-carbonate vein deposits. The work resulted in recognition of numerous copper occurrences, the most significant of which is the Magnum deposit (**Fig. 3**). The Eagle vein at the Davis-Keays copper prospect underwent surface and underground development at the same time as the Magnum deposit, with semi-proven reserves in 1971 of 1,119,089 tonnes grading 3.43 per cent copper (BC Minfile 094K 012).

In the southern portion of the project area, the Bronson, Book 6, Book 9/10 and Toro prospects also received advanced exploration. Subsequent to cessation of mining in 1974, major exploration activities ceased in the region until the early 2000's when Archer Cathro and Associates Ltd., carried out an regional exploration program to assess the district for Iron-Oxide-Copper-Gold (IOCG) mineral potential. The exploration program consisted of regional and detailed prospecting, regional silt and pan

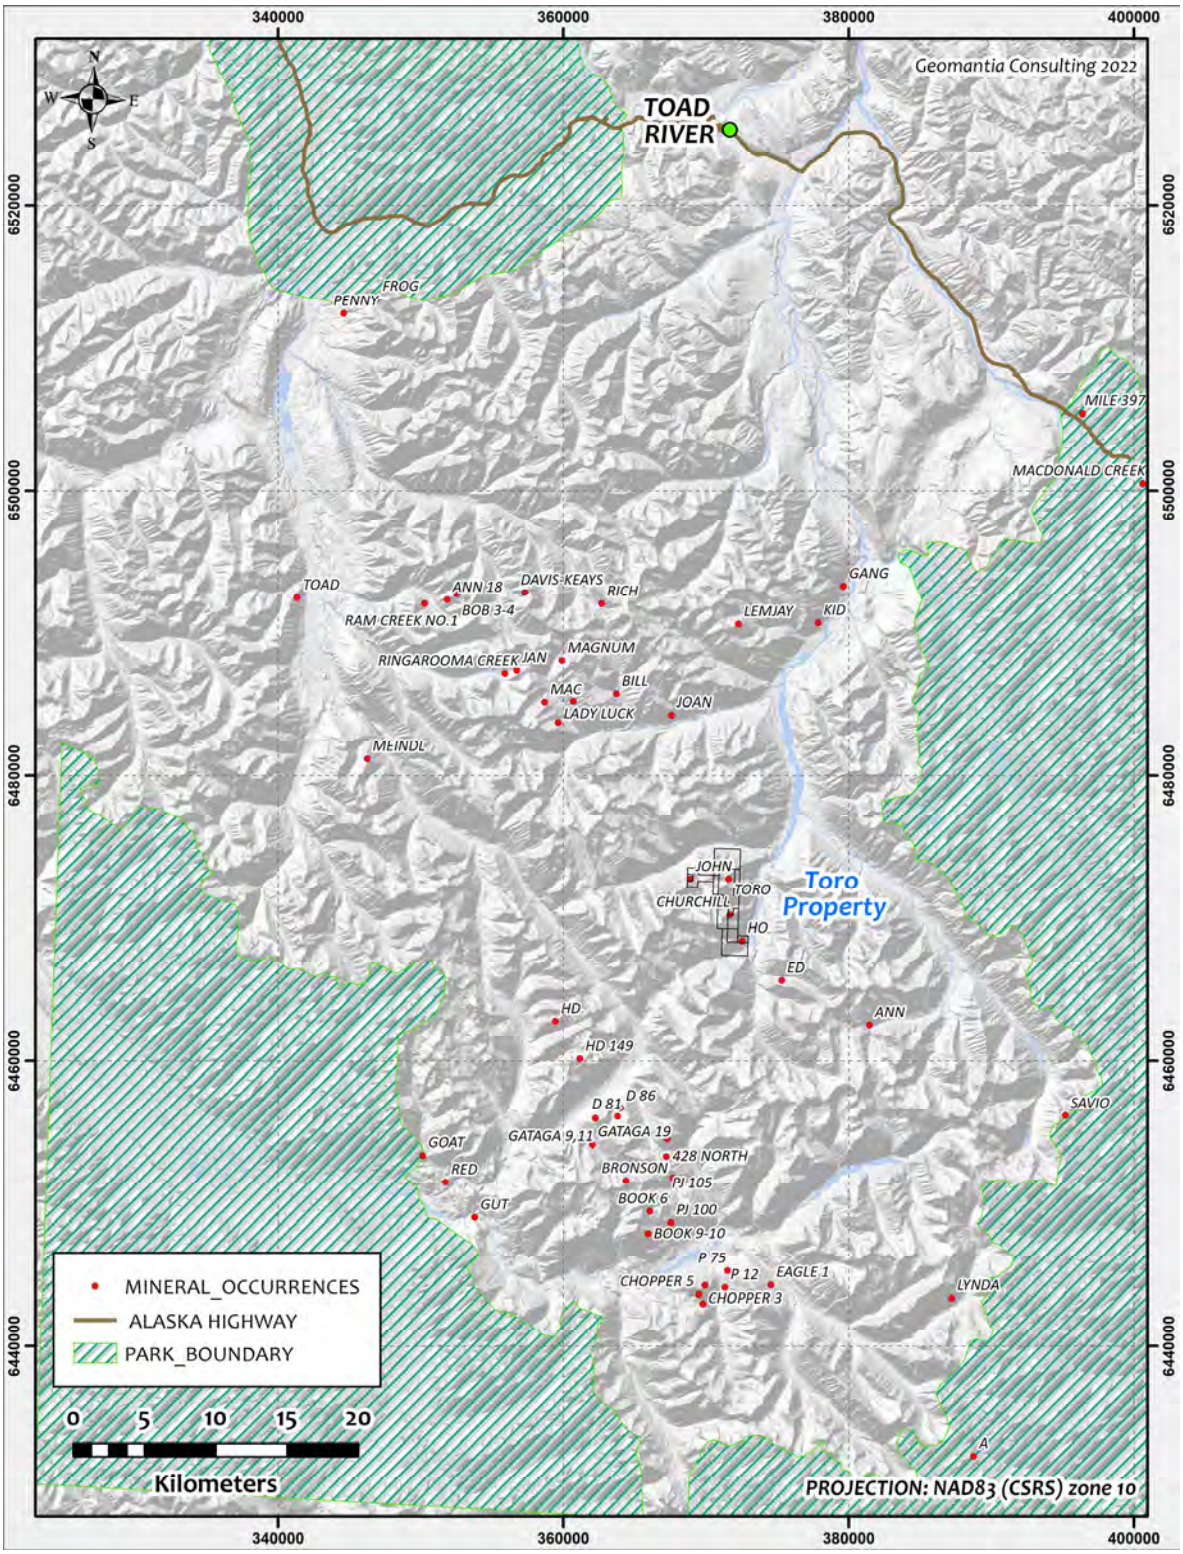

**FIGURE 3:** Regional Mineral occurrence Map, Muskwa Region.

sampling, mapping and prospect scale-soil sampling. A small 420.6 m drill program was carried out on the Matnik occurrence.

A property-wide geophysical survey was flown by Sanders Geophysics Ltd. of Ottawa, Ontario. Approximately 9,002 line kilometres of airborne magnetic data were acquired of the project area. The traverse lines were flown at 400 m spacing and oriented at 58° with control lines at 2 km spacings and oriented at 148°. The survey was flown at a height of 150 m above the minimum drape surface. Raw magnetic data was processed by Aurora Geosciences Ltd. to remove the underlying regional magnetic gradient. Some smaller exploration programs were completed between 2005 to 2008 by Aries Resource Corp. and Action Minerals Inc. An airborne electromagnetic survey was conducted for Aries Resource Corp. during the 2005 program. A limited rock prospecting and reconnaissance drill program was also completed in 2019 by Fabled Copper Corp.

Earliest exploration on the Toro property was carried out by Canex Aerial Exploration Ltd. in 1966 on the 3.2 km long, copper bearing Toro quartz vein system. The program included geological mapping, sampling and 211 m of diamond drilling from two short adits having an aggregate length of 24.4 m (Preto, 1971). Copper grades appeared to significantly decrease at depth where the drilling intersected the veins. The drill intersections averaged 0.66% copper over 4.1 m. These disappointing drill results are difficult to reconcile with a 1970 feasibility study, by MacDonald Consultants that calculated proven and probable reserves at 1,423,860 tonnes grading 3.42% copper. In 1971, Chapman, Wood & Griswold calculated 'semi-proven' and probable reserves at 1,574,453 tonnes grading 3.38% copper. Both studies concluded that the possibility of defining more reserves at depth is excellent (BC Minfile 094K 050).

Archer Cathro and Associates Ltd. carried out a work program in 2005 which consisted of collection of 57 rock samples, 233 soil samples and 5 silt samples and 5 pan samples. These data were re-evaluated in 2019 by Fabled Coppper Corp. Additionally a small prospecting program as carried out by Fabled Copper in 2019. Twenty-five samples with copper grades ranging from 0.01 to 4.34 % Cu were collected across the Toro claims. No exploration work has occurred on the Toro property since 2019.

## 5.0 REGIONAL GEOLOGY and GEOPHYSICS

The following description of regional geology is summarized from Carne (2006). The Toro property and surrounding Cu-Co vein occurrences are located in the Cordilleran Foreland Belt in the northern Rocky Mountains. The district is characterized by broad belt of sedimentary rocks that have undergone polyphase deformation, the youngest of which has resulted in open to tight and upright to inclined folding and a stack of northeast verging thrust or reactivated reverse faults (**Fig. 4**). The overall structural grain throughout the Rocky Mountains is predominantly northwest. The main structural feature in the Cu-Co vein district is the Muskwa Anticlinorium, a major north-northwest trending window that exposes rocks as old as Middle Proterozoic (Helikian).

The pre-Paleozoic package is collectively referred to as the Muskwa Assemblage and consists of a 6400 m thick succession of argillaceous to fine grained siliciclastic strata and carbonates. Seven formations of Proterozoic age are represented in the anticlinorium (**Fig. 5**). From oldest to youngest, with approximately true thickness, they are the Chischa Fm (940 m), Tetsa Fm (320 m), George Fm (360-530 m), Henry Creek Fm (460 m), Tuchodi Fm (1500 m), Aida Fm and Gataga Fm (3000 m together). Paleozoic units unconformably overlie the Proterozoic rocks along a Lower Cambrian erosional surface.

The Tuchodi Fm is the oldest outcropping unit occurring with the Cu-Co district. It comprises medium to thin bedded quartzite and quartz flooded dolomitic siltstone and argillite. This formation is relatively resistant to weathering and often forms an obvious bench on hill slopes where overlain by the more recessive weathering Aida Fm and Gataga Fm.

The Aida Fm conformably overlies the Tuchodi Fm and is composed of buff weathered calcareous and dolomitic siltstone and mudstone with minor amounts of sandstone. Two generations of penetrative slatey cleavage are well developed in the rocks of this formation.

The Gataga Fm conformably overlies the Aida Fm and is characterized by black carbonaceous shales. Its rocks are well cleaved and dark weathered. Their lithologies and the presence of turbidite structures and soft sediment deformation indicate that the Aida Fm and Gataga Fm were deposited in a deep water setting (Ross et al., 2001).

Paleozoic stratigraphy in the region is Cambrian to Devonian in age. These strata unconformably

overly the Proterozoic formations and are mainly composed of carbonaceous and siliceous units, including limestone, dolomite, quartzite and quartz pebble conglomerate.

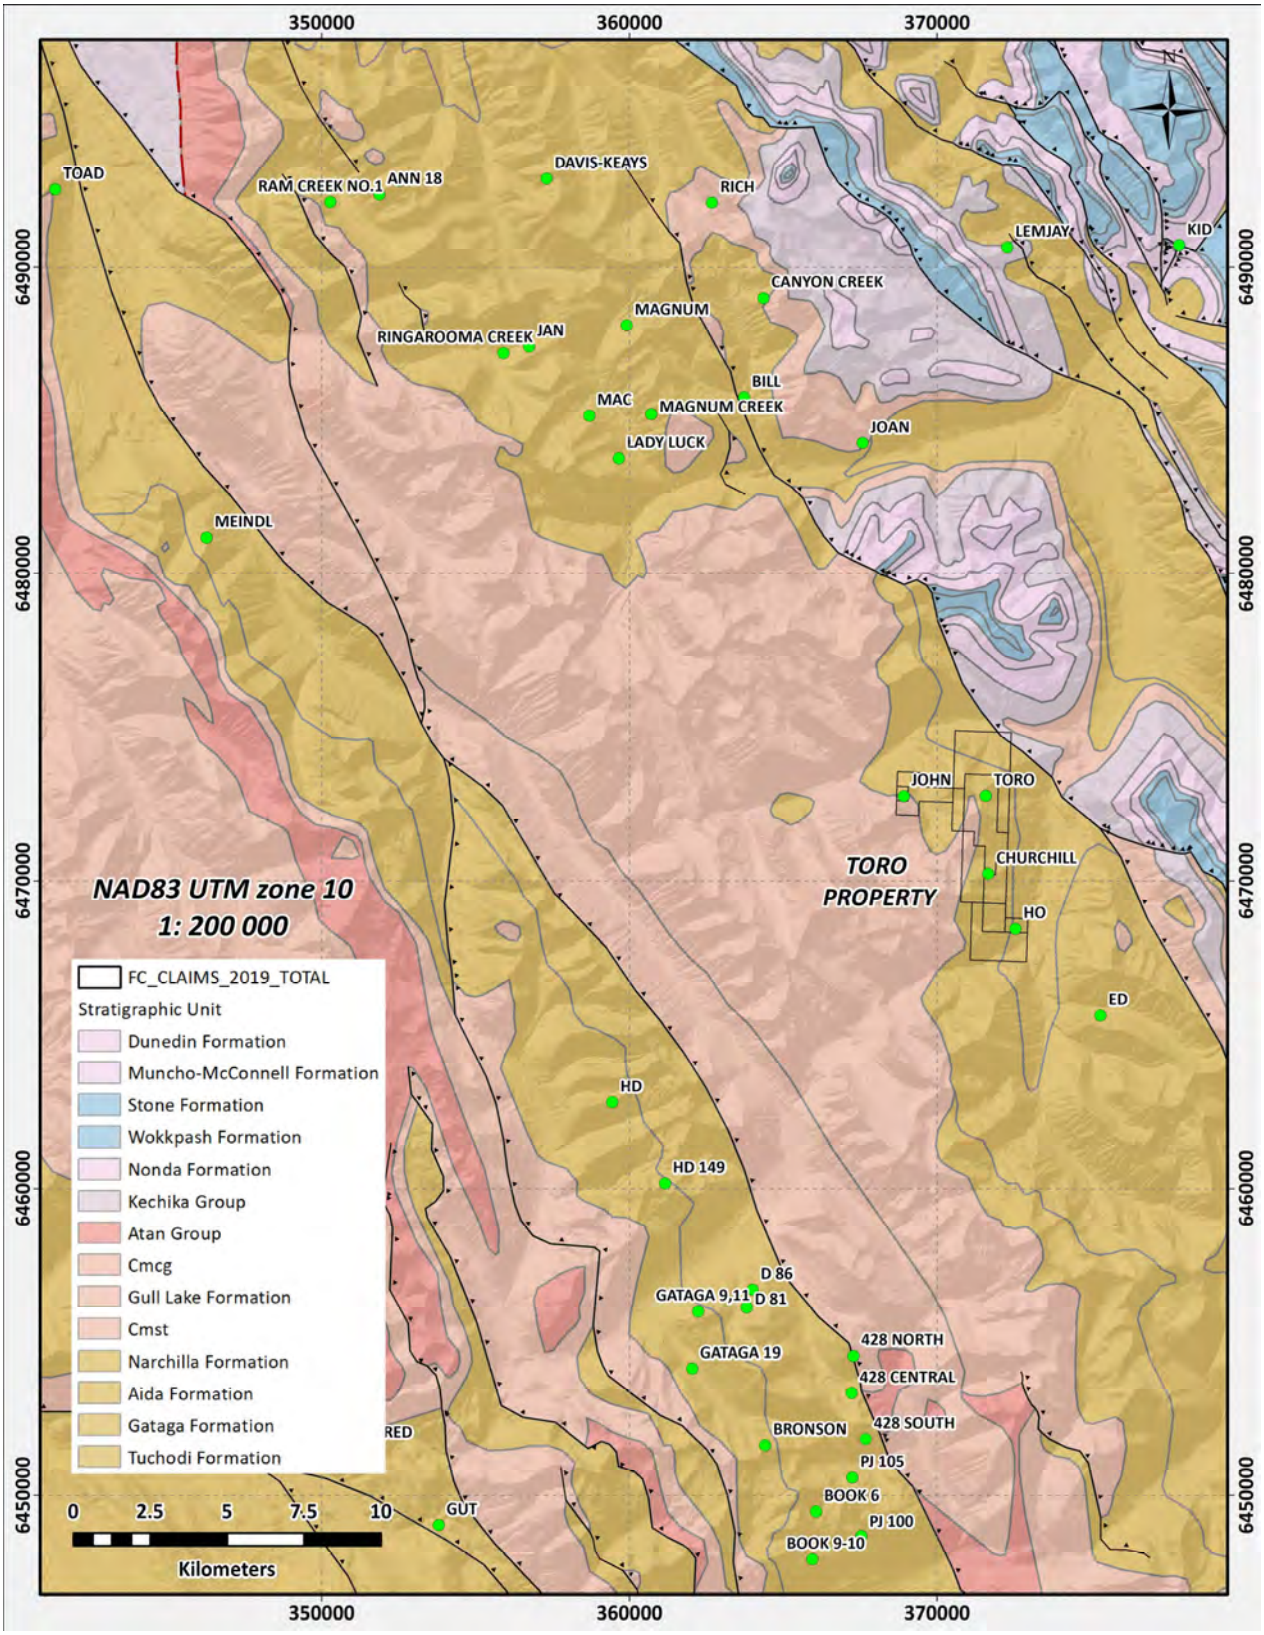

**FIGURE 4:** Regional Geological Setting of the Toro Property. Source - Cui et al. (2017).

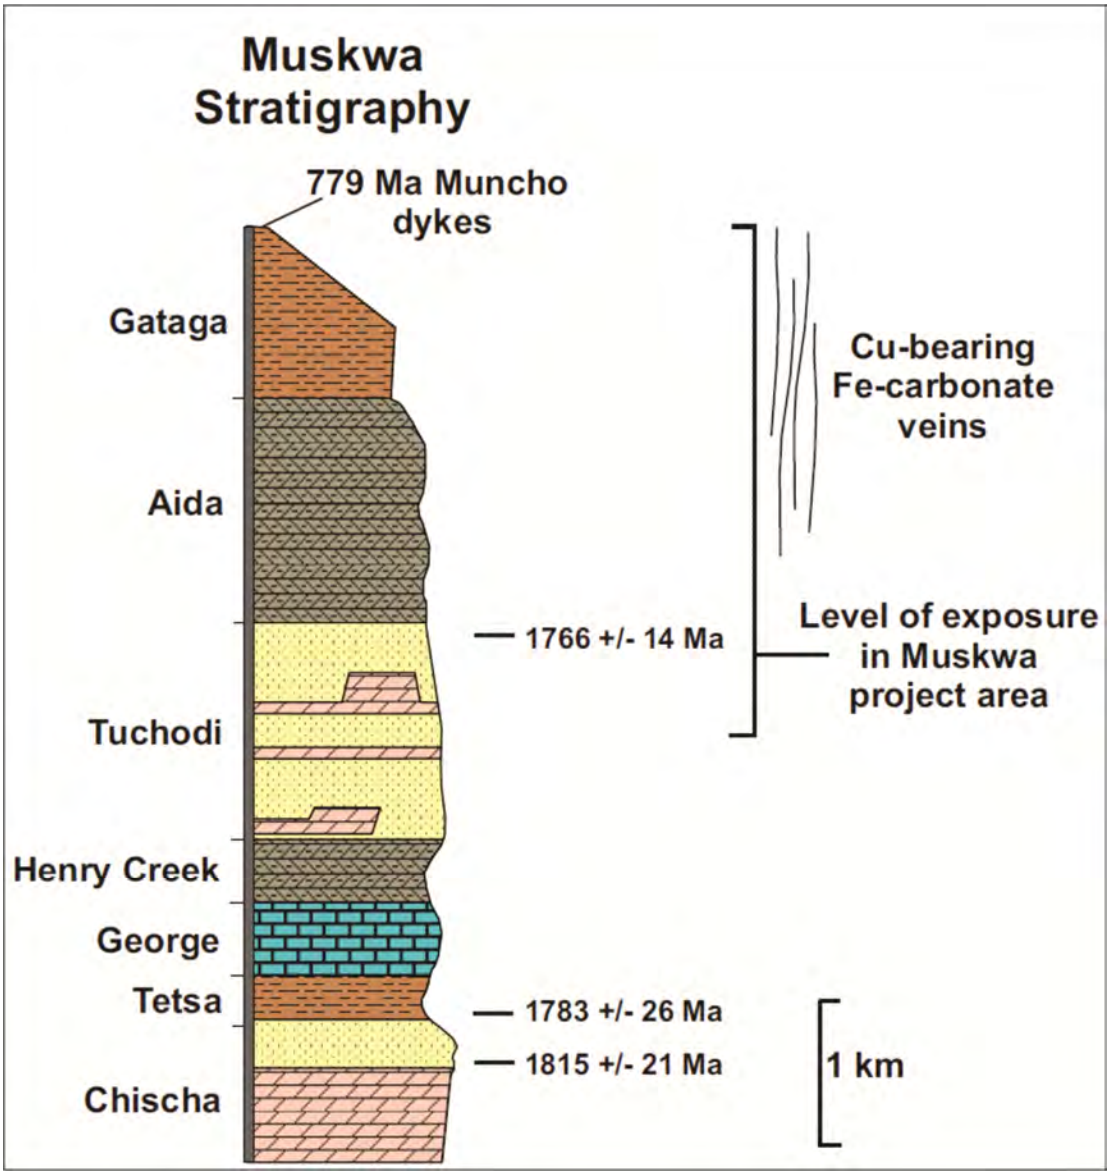

**FIGURE 5:** Stratigraphic column summarizing generalized Proterozoic stratigraphy in the Muskwa Region (Source – Carne, (2006))

The Proterozoic formations are crosscut by a series of apparently Hadrynian aged gabbro and diabase dykes. The dykes range between 5 to 35m in width and follow the main north-northwest structural orientation of the area. The majority of the dykes are moderately to strongly magnetic. They form prominent linear features that resist weathering.

Low grade metamorphism, mainly subgreenschist, is evident throughout the Proterozoic sedimentary package. Contact metamorphism along the periphery of the dykes is rare but, where present, is associated with sericite and chlorite alteration.

Thrust faults, reverse faults and moderate folding characterize the structural history of the area. Late Helikian or early Hadrynian structures are represented by high angle fault zones that have been intruded by dyke swarms. These structural zones are considered to be deep-seated and have been observed to be up to 180 m wide, hinting at an extensional tectonic environment. Their inferred strike lengths are in the order of tens of kilometres. Copper bearing quartz carbonate veins were emplaced along these same structures and are mainly found adjacent to the diabase units. Shearing is common along the dyke contacts with the wallrocks and veins.

Low angle, westerly dipping thrust faults have in some areas stacked Proterozoic basement rocks above the Paleozoic cover rocks. These faults are north-south trending and extend over hundreds of kilometres. Faults and folds in the Muskwa area developed during Jurassic to Tertiary times.

Regional airborne magnetic and gravity surveys are available for the project area from Natural Resources Canada (NRCAN; **Figs. 6 & 7**). The aeromagnetic data consists of residual total field and first vertical derivative data. Seven airborne gravity datasets are available including:

i) Bouguer anomaly data
ii) First vertical derivative
iii) Free air gravity data
iv) Horizontal gravity gradient data
v) Isostatic residual gravity data
vi) Total observed gravity data
vii) Gravity anomaly data

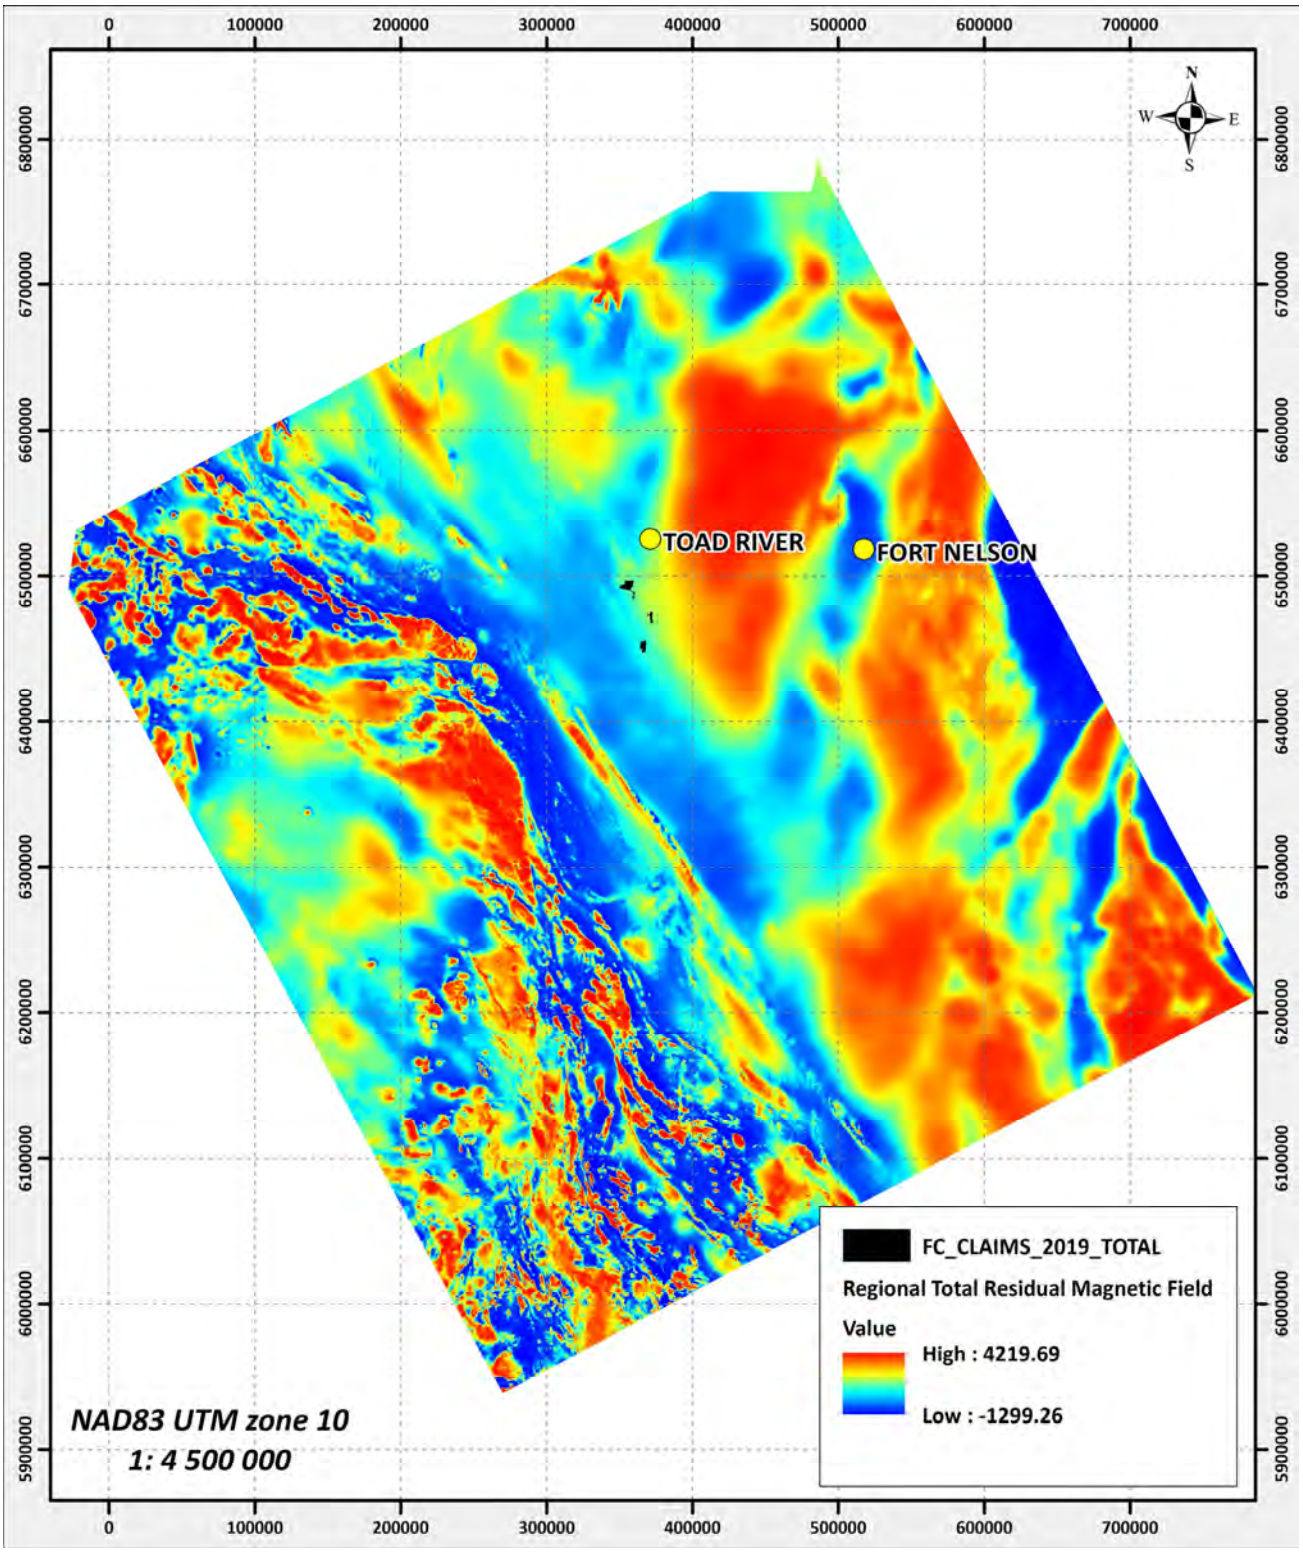

**FIGURE 6:** Total Residual Magnetic Field Data, Muskwa Region (Source – NRCAN)

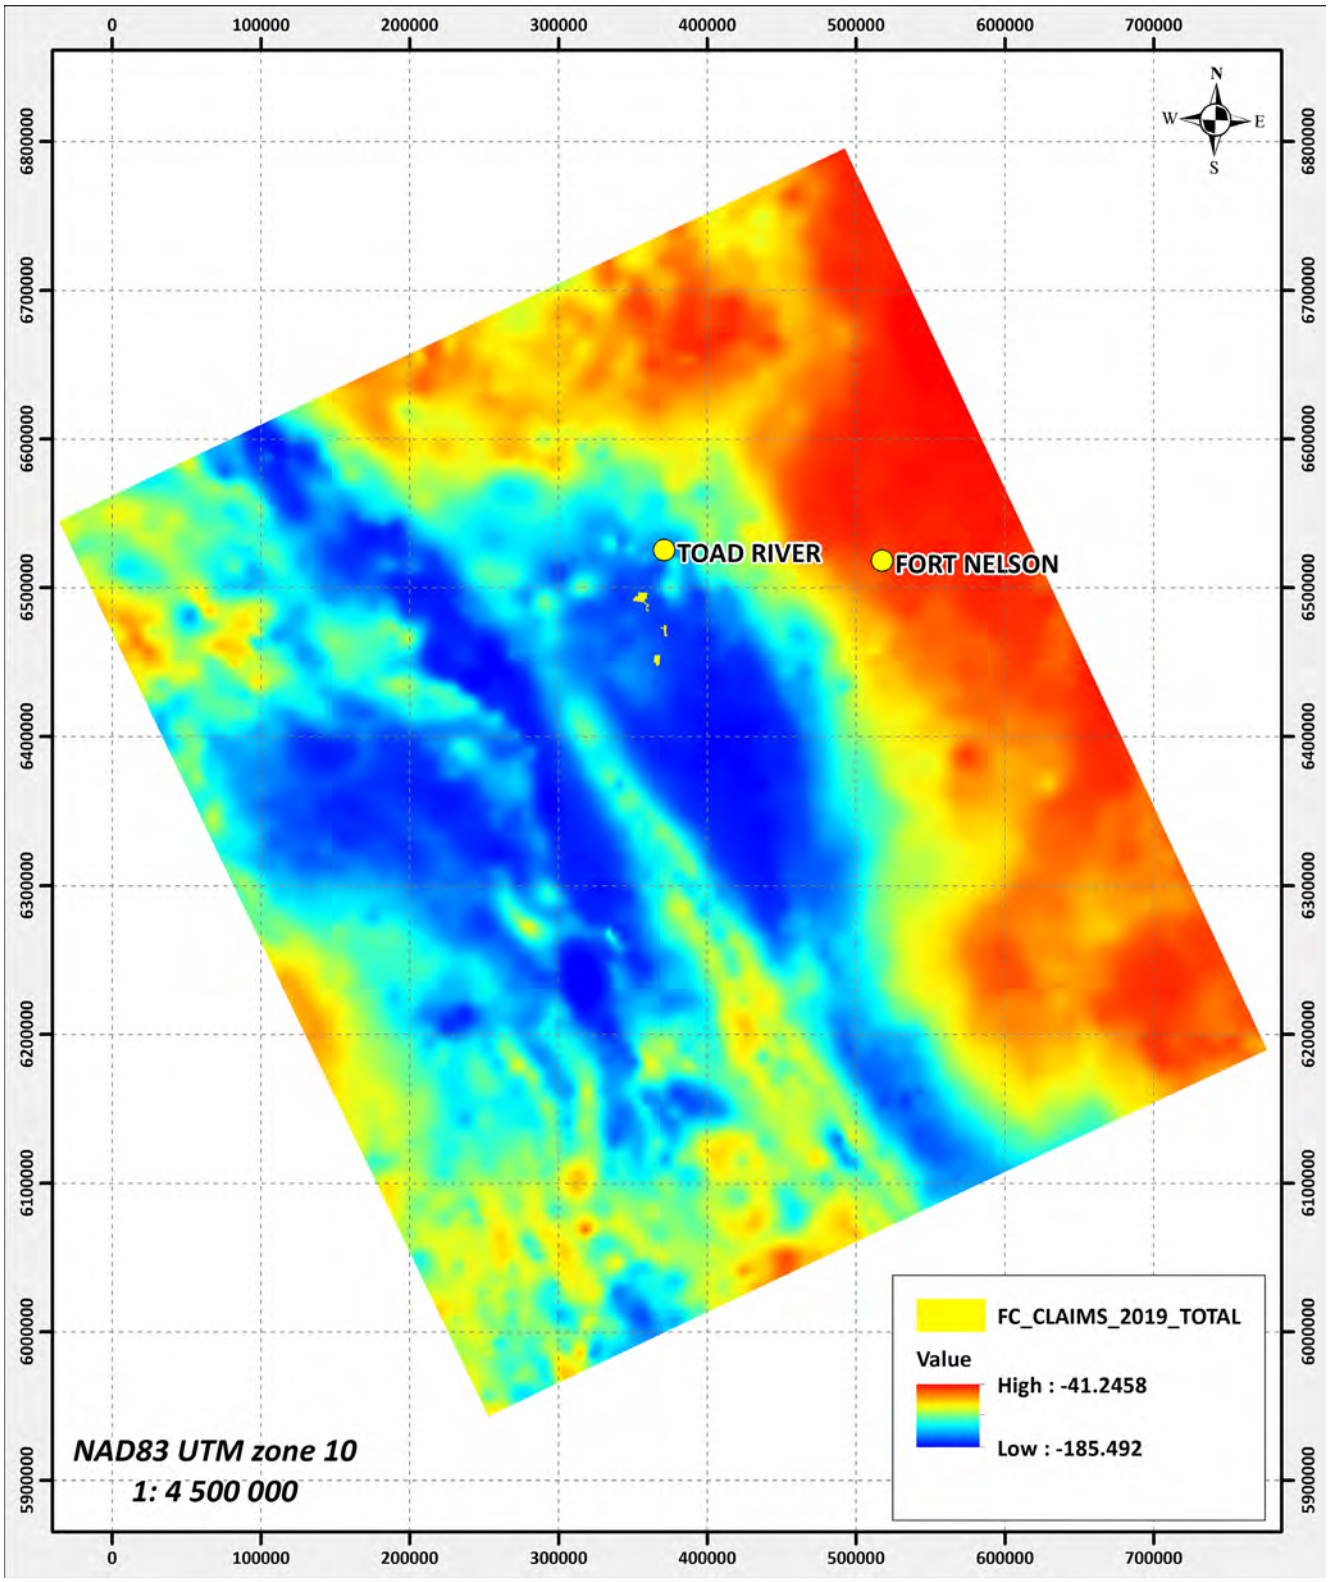

**FIGURE 7:** Regional Bouguer anomaly gravity data, Muskwa Region (Source – NRCAN)

Integrated gravity and magnetic data are critical targeting tools for IOCG mineralization. In many known deposits, mineralization occurs at the edge of a magnetic high and in the center of the residual positive gravity anomaly (Austin and Foss 2012; **Fig. 8**). Several small positive anomalies occur within the regional gravity dataset although they are subdued intensity as a result of the large positive gravity anomalies associated with Palaeozoic stratigraphy located on the eastern side of the data (**Fig. 9**). A comparison of the positive gravity anomalies with residual aeromagnetic data indicate some coincidence with gravity highs with the edge of regional positive magnetic anomalies although better higher resolution datasets are needed to better demonstrate this trend (**Fig. 10**).

## 6.0 MINERALIZATION AND DEPOSIT MODELS

Copper mineralization throughout the Muskwa region is associated primarily with copper bearing quartz iron carbonate veins emplaced along NNW, N, NNE and NE near vertical structures. The veins often have strike lengths over 1 km and range from stringer zones to widths of 4 m. Chalcopyrite and malachite are the dominant copper minerals with minor bornite and chalcocite. Mineralization consists of lenses to stringers to blebs of copper minerals in the host veins. The majority of the mineral occurrences host patchy and sporadic mineralization throughout the structures. Copper mineralization is often better developed at the contact zones between the quartz-iron carbonate vein systems and adjacent diabase dykes.

In addition to the copper-bearing quartz iron-carbonate veins, several iron oxide breccia zones have been discovered in the region. The Dieppe and Matnik occurrences have both reported the presence of hematite-bearing breccias.

The IOCG deposit model was first suggested by Archer Cathro and Associates Ltd in 2005 for the Cu-Co mineralization present in the region. Iron-Oxide-Copper-Gold deposits are considered to be (i) magmatic-hydrothermal deposits containing economic quantities of Cu and Au, (ii) are structurally controlled containing significant breccia volumes and are (iii) often associated with pre-ore sodic or sodic-calcic alteration (Groves et al. 2010). Additionally, these deposits have abundant low-Ti iron oxides and/or iron silicates associated with, but generally paragentically older than the Cu-Fe sulphides (Groves et al. 2010). Pyrite is generally low in overall abundance and widespread quartz veining or silicification is absent (Groves et al. 2010). Finally, IOCG deposits have clear temporal relationship to major magmatic intrusions. These systems are theorized to transition into the epithermal mineralizing environment if erosion is minimal and permits preservation.

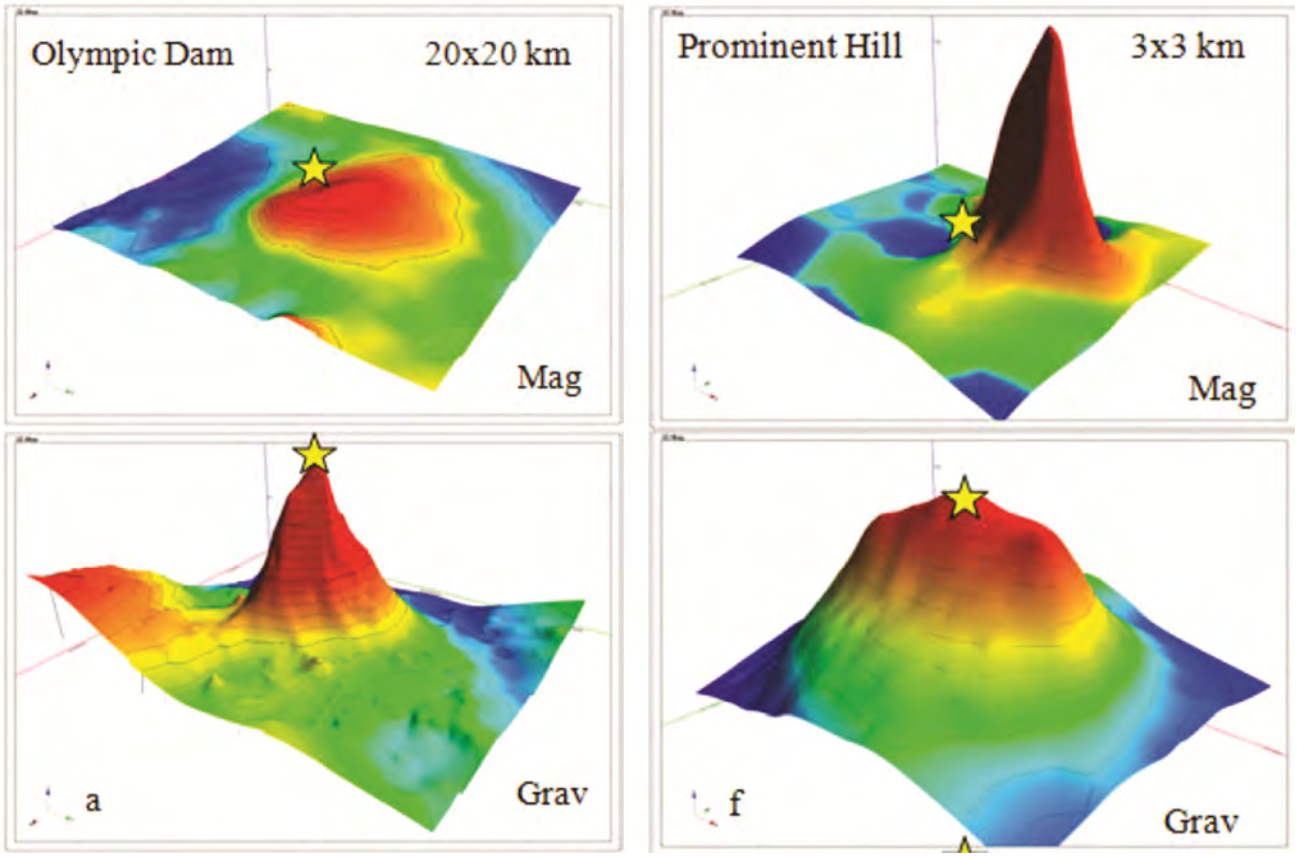

**FIGURE 8:** Examples of overlapping residual gravity and magnetic anomalies over known IOCG deposits (Source – Austin and Foss, 2012).

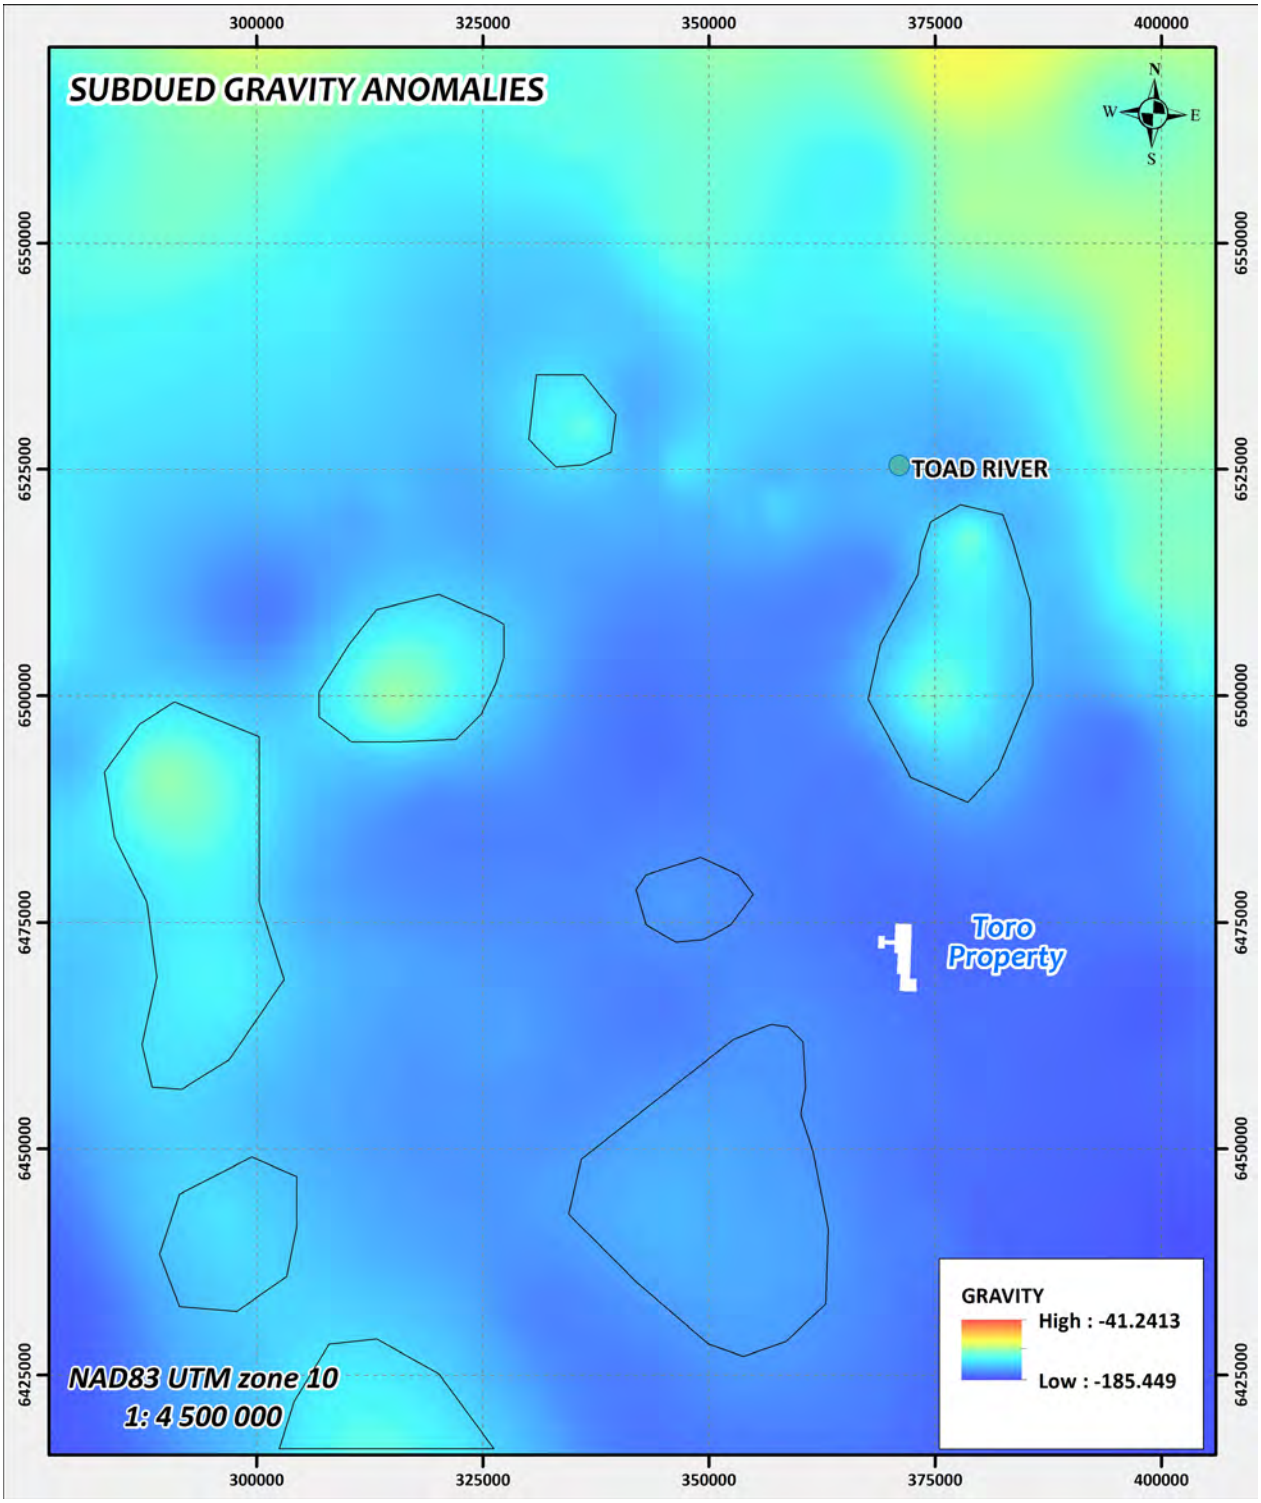

**FIGURE 9:** Regional positive Bouguer gravity anomalies in the Muskwa Region.

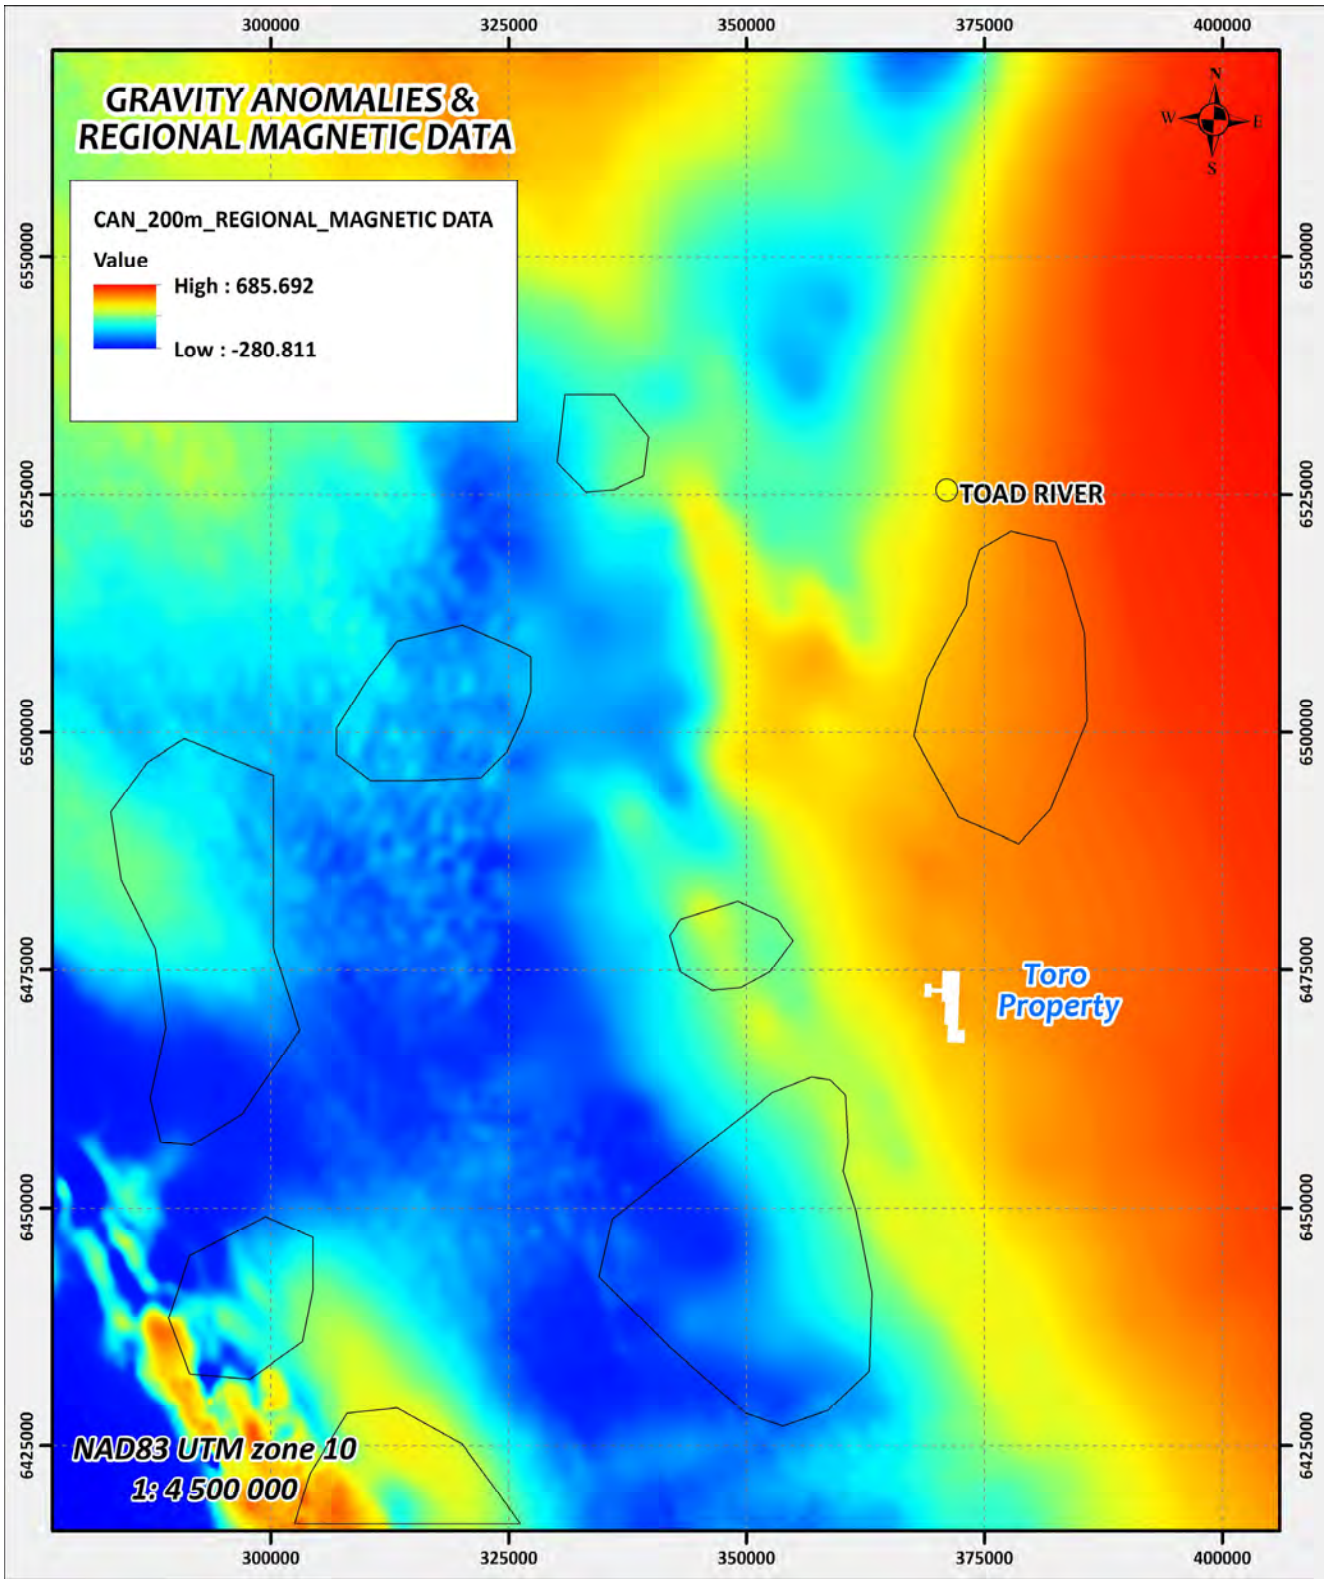

**FIGURE 10:** Location of positive gravity anomalies adjacent to regional aeromagnetic positive anomalies.

Iron oxide-copper-gold (IOCG) mineralization is associated with the pathfinder elements **Ag, As, Au, Ba, Bi, Ca, Cd, Ce, Co, Cr, Cs, Cu,F, Fe, K, La, Mn, Mo, Ni, S, Sb, Se, Sn, Te, U and W** (Wang et al. 2013; Hill et al. 2014;) and are often preserved within hydrothermal alteration halos that can be linked to mineralization. As an example, an alteration signature may progress from regional Na-enriched, K-depleted alteration to camp-scale Mn, K, and Ba enrichment and Na-depleted alteration to deposit scale alteration enrichment in Ag, Au, Bi, Cu, Fe, K, Mo, Sb and U (Porter 2010). Univariate and multivariate geochemical analysis of historic rock, silt and soil data completed in 2019 indicate that pathfinder elements associated with Cu mineralization within Muskwa region are similar to pathfinders present in known IOCG deposits (Cu-S-As-Ag-Co-Fe and Ni).

## 7.0 TORO PROPERTY GEOLOGY AND 2021 PROSPECTING RESULTS

The Toro property is underlain by interbedded dolostone and slatey argillites of the Proterozoic Aida Formation and red-weather siliciclastic sandstones and conglomerates of the unconformably overlying Cambrian Sylvia Formation. East of the main Toro mineral occurrences clastic sedimentary rocks of the Tuchodi Formation occur. Cambrian stratigraphy occurs predominantly within the western half of the property and Proterozoic stratigraphy in the east (**Fig. 11**).

The Proterozoic sedimentary rocks are cut by several large, NNE-trending diabase dikes which, in the western area of the showings, are truncated and unconformably overlain by varicolored clastic Cambrian strata of the Sylvia Formation (Preto, 1971). Taylor et al (1973) interpreted a major northwest-trending southwest-dipping thrust fault to be located approximately one kilometer northeast of the property.

Copper mineralization occurring in the quartz-carbonate veins appears to be highly variable and discontinuous. Preto (1971) suggested that the better mineralized veins are older than the dikes, occurring either as inclusions inside dikes or as panels along or near the sides of dikes. The Toro claims encompass four mineral occurrences summarized below with information from the B.C. Minfile. The main showings outcrop on top of a 2438 m high north-south trending ridge. The remnants of an old helicopter pad on the ridge top and other old workings are still visible.

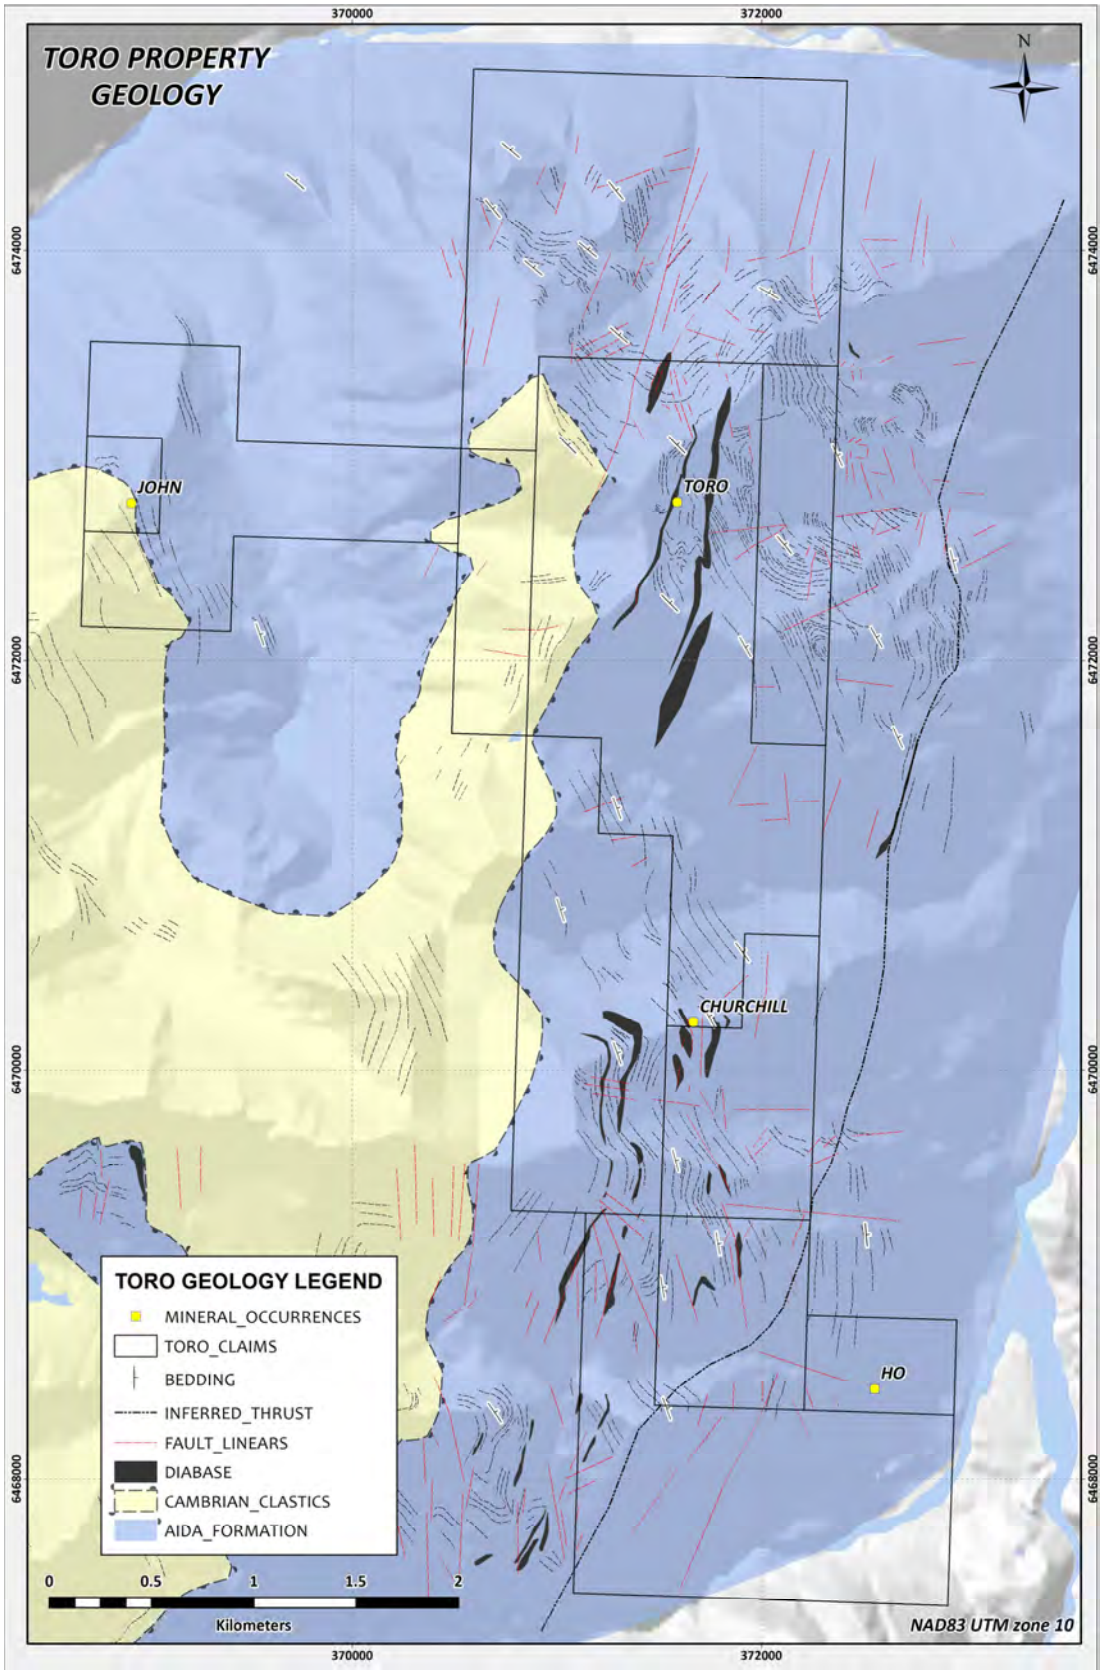

**FIGURE 11:** Toro property digital geological interpretation

The rocks are locally strongly folded about a northwesterly axis. Bedding strikes around 315˚ and dips moderately southwest or locally northeast. The structural fabric of the area strikes southeast and dips moderately to the southwest (**Fig. 11**).

A large-scale open syncline with NE-oriented axial plane and presumed WSW plunging fold axis is defined by the rotation of bedding from NNW in the south to NW in the north of the property (**Fig. 11**). Additionally a significant zone of deformation and alteration is located at along the eastern boundary of the property. The Ho mineral occurrence is located within this zone. This zone may represent a faulted contact between the Aida and the Tuchodi formation.

## 2021 Toro Property – Rock Prospecting Program

A total of three and half field days were spent on the Toro property reviewing the main mineral occurrences and collecting samples to verify presence of economic quantities of copper mineralization. Thirteen samples weighing between 0.5 and 2.2 kg were collected and shipped to ALS Chemex of North Vancouver, BC, for processing and analysis. A blank and two copper standards (OREAS 922 and 928) were included for Quality Control and Quality Assurance (QC/QA) purposes. Samples are placed in clear plastic bags together with a waterproof paper ticket depicting a unique sample number. Each bag is tied with cable ties and labelled with permanent marker. For sample preparation and analysis, the ALS geochemical methods Au-ICP21 and ME-ICP61were used. Overlimit values were analysed using the ME-OG62, Cu-OG62 and Pb-OG62 methods. Details of each analytical method are provided in Appendix III. Field logs are presented below and a summary of rock geochemical results follows.

**July 23:** The terrain containing the Toro, John, Churchill and Ho Occurrences were overflown. The Ho Occurrence was prospected by G. Henriksen (GH), R. Campbell (RC), G. Giga (GG) and R. Grenier (RG), starting on the west branch of Churchill Creek then following an old dozer trail upwards towards the occurrence in claim 1063714. 5 samples of float were collected and traversing reached to within 65 meters of the exposed Ho Vein. Approximately 4.5 km of traversing was completed by each prospector.

**August 24:** GH, RC, GG and R.G prospected (approx. 4 km. of traversing each) along a valley, east and downslope of the supposed location of the John Occurrence. 3 samples of float were collected, 1 just east of the property and 2 on claim 1024157.

**September 1:** GH and RC were flown to the west bank of Churchill Creek, just north of the northeast corner of claim 1023665. One half a day each was spent prospecting through the eastern parts of claims 1023665 and 1063714, downslope of anomaly Target 11. Five samples of float were taken (2 in claim 1023665 and 3 just north of this claim) and each prospector performed 2 km. of prospecting.

**September 2:** GH and RC each spent ½ a day (1 km. of traversing each), prospecting in claim 1024158, near the location of Target 11 and upslope of the prospecting of Sept. 1. A vein was observed in place across a ravine, along strike north of the Ho Occurrence. No samples were collected, since topography was too steep and no mineralized float was observed.

**September 7:** GH and RC east spent ½ a day prospecting northeast along a tributary of Churchill Creek and then along a switchback dozer trail. west of the supposed location of the John Occurrence. Each prospector completed approximately 3.5 km. of traversing with claim 1024157 being reached, but the vein wasn't observed and no samples were collected.

The Ho and John Occurrences and Target 11 Anomaly on the Toro Property were prospected on July 23, Aug. 24, Sept. 1, Sept.2 and Sept. 7. Thirteen samples of float were collected (**Fig. 12**). Assay results are presented in **Table 2** and Cu assay values are displayed on **Figure 13.**

Ho – Target 11

On July 23, a prospecting traverse was started on the west branch of the Churchill Creek and continued up-slope along an old dozer switchback trail to within 65 meters, at a slope of 37 degrees, of the Ho Vein. The vein is exposed on a northeast trending rock face at an altitude of ~ 1400 meters. Five examples of quartz-carbonate float (D723211 to D723214), with Cu mineralization and shale-siltstone fragments, were sampled on claim 1063714 at elevations of 1166 to 1365 meters. Four of the five samples contained 1.155 to 1.46 % Cu and the fifth sample (D723210) collected the farthest from vein exposure, at the lowest elevation, assayed 0.664% Cu. The five samples contained 1 to 5 % chalcopyrite, abundant malachite and trace bornite.

Target 11 is comprised of 2 anomalies located 1 and 1.35 km. north of the exposure of the Ho Vein. On Sept. 1, the downslope area east of the anomalies was prospected and five samples (D723517 to D723521) of float were collected at elevations of 1111 to 1154 meters. The highest Cu content (0.97 %) was

found in sample D723518 which was comprised of weathered wacke with quartz-sulphide (1 % chalcopyrite and trace azurite and bornite). Samples D723517, 520 and 521, of quartz-carbonate veining with shale-siltstone fragments, minor chalcopyrite and trace amounts of bornite, contained 0.113, 0.299 and 0.375 % Cu, respectively. A sample (D723519) of wacke, with 3-5 % pyrite, assayed low in Cu (0.0052 %).

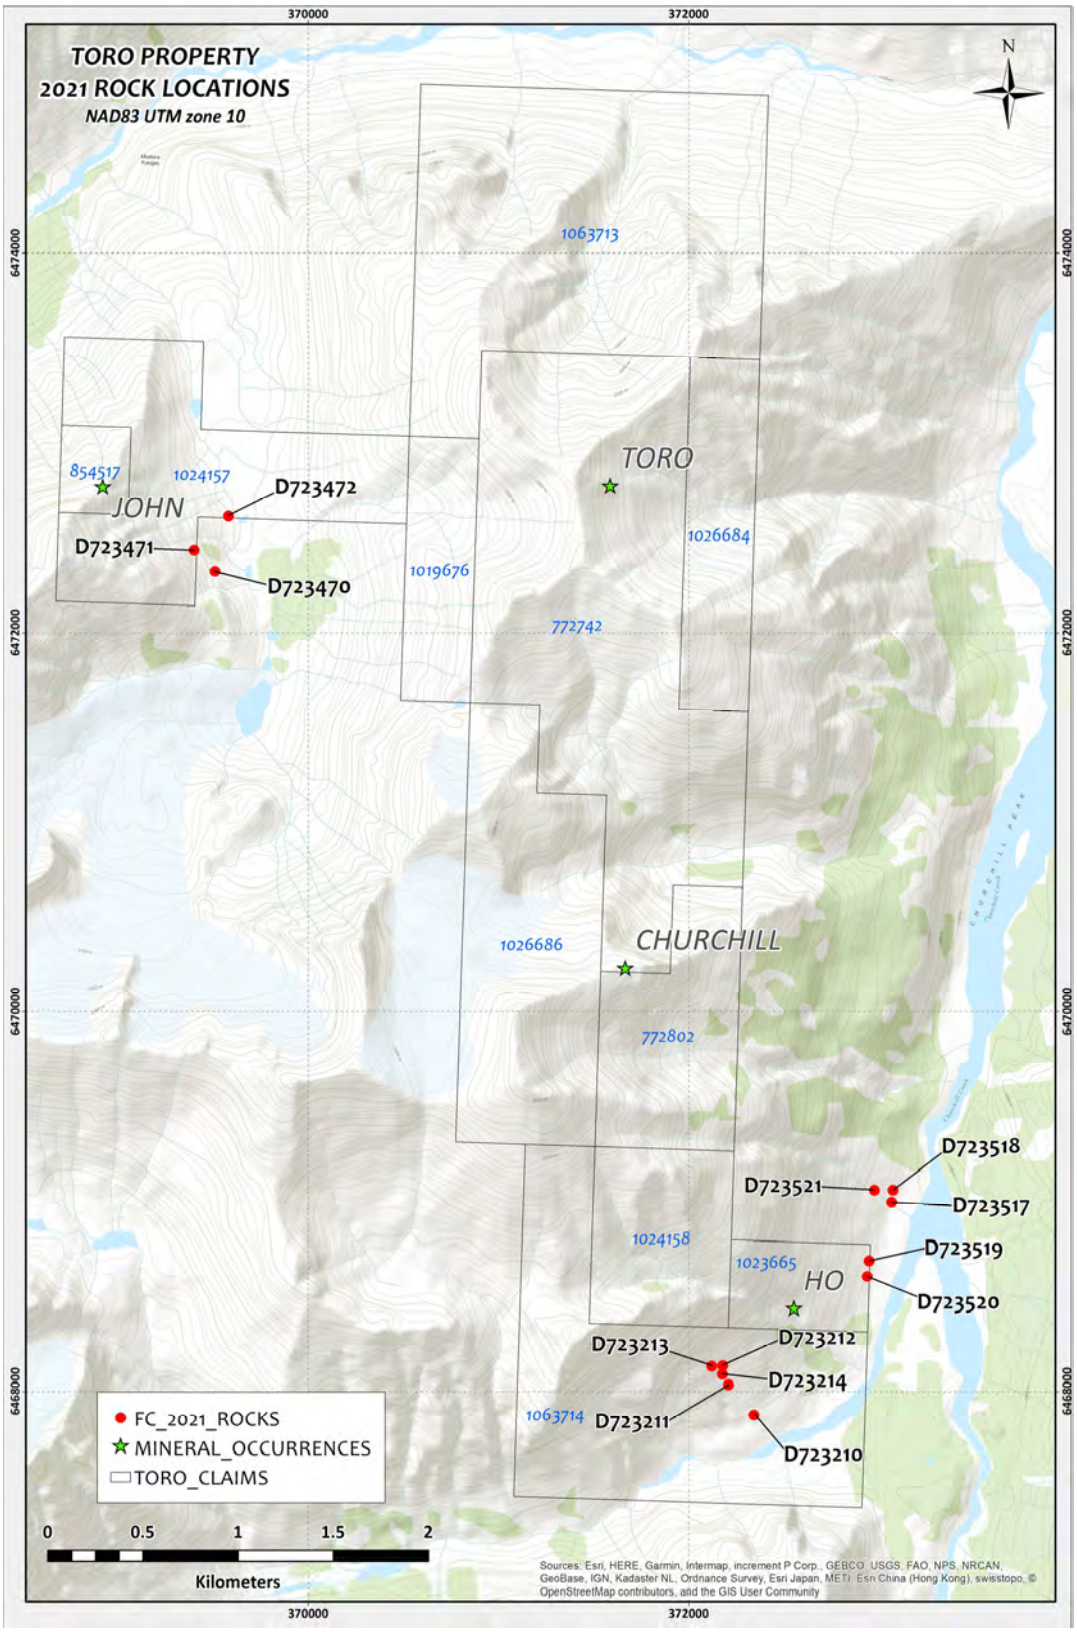

**FIGURE 12:** Location of 13 rock prospecting samples collected in 2021 on the Toro property.

**Table 2:** Toro 2021 rock prospecting results

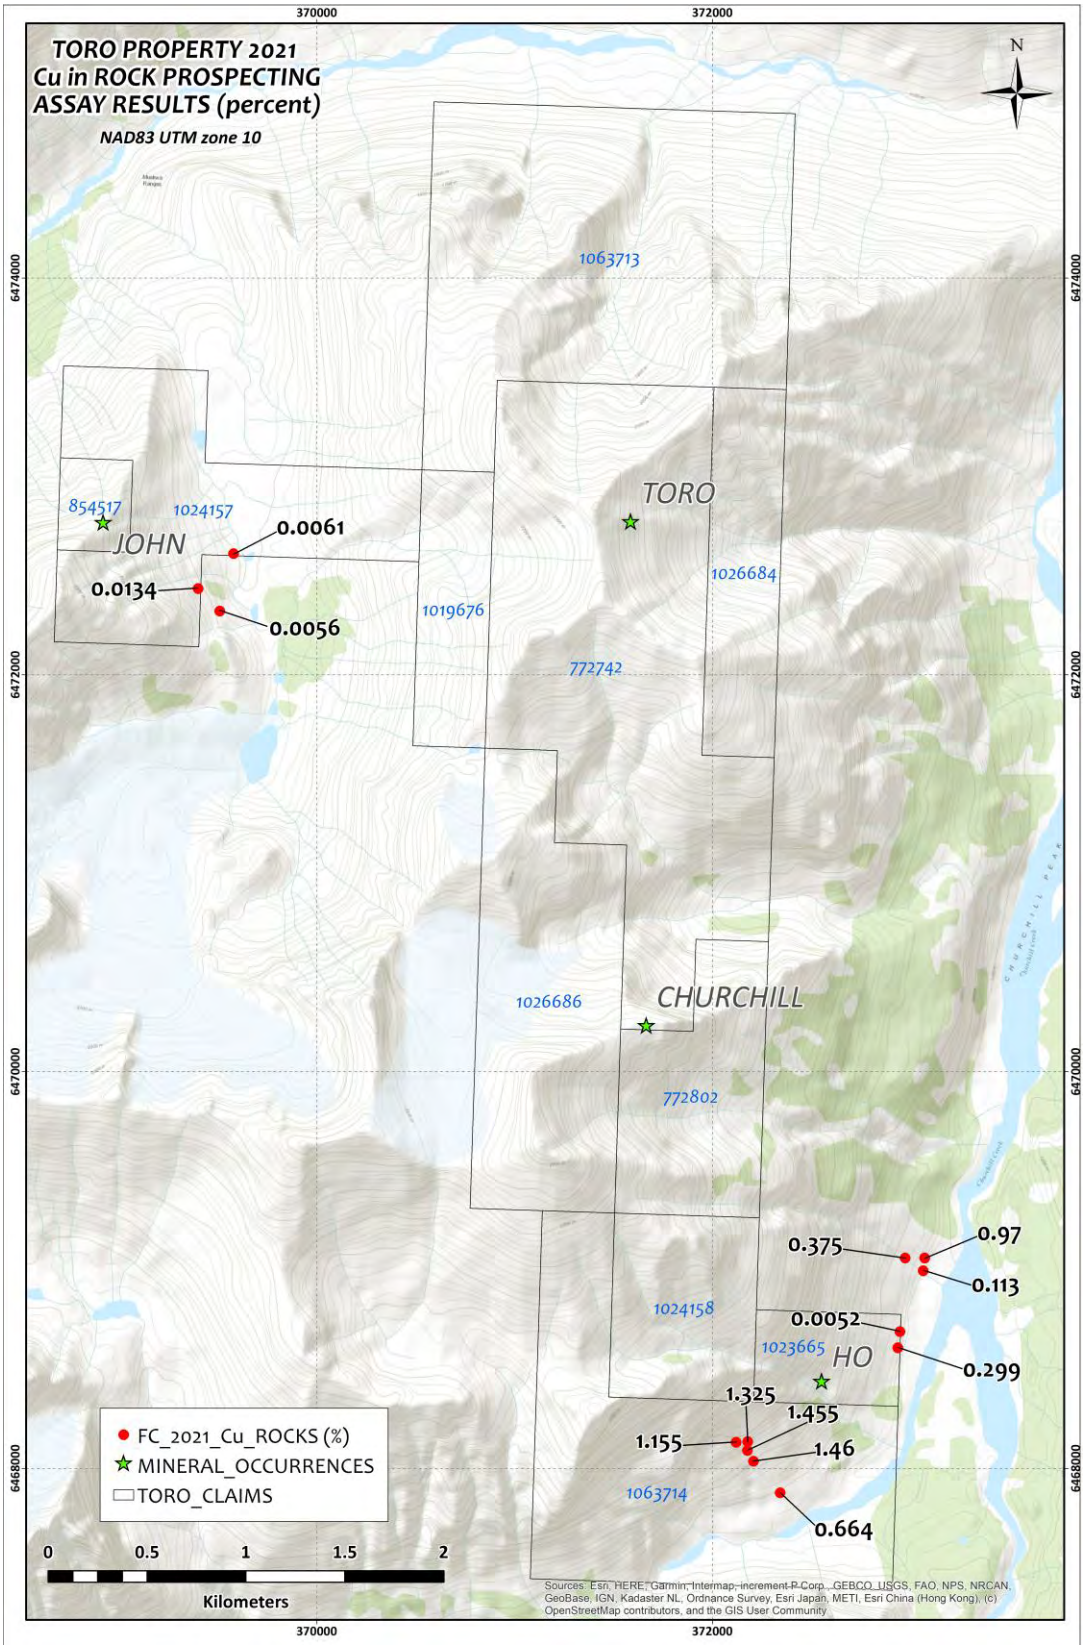

**FIGURE 13:** Copper in rock results for 13 rock prospecting samples collected in 2021 on the Toro Property.

While prospecting the anomalies of Target 11 on Sept. 1 an exposed quartz vein was seen upslope to the west. On Sept. 2 the helicopter placed the crew upslope on claim 1024158 and 2 quartz veins, striking ~ 355 degrees at an altitude of 1767 meters, were observed across an east trending ravine to the north. These veins lie 1.1 km. north along strike of the Ho Vein exposure.

John

The John Occurrence wasn't found or seen in outcrop while prospecting a valley (Aug. 24) and a valley-old switchback dozer trail (Sept. 7), east and northwest, respectively, of the supposed location of the occurrence. Three examples (samples D723470-472) of quartz-carbonate float were collected at elevations of 1693 to 1783 meters. These samples contained no sulphide content and assayed low in Cu (0.0056-0.0134 %). The location where 2019 sample Y646006 was collected was found near the southern boundary of claim 1024157.

Toro and Churchill

The locations of the Toro and Churchill Occurrences were overflown on July 23. The Toro Veins and some old workings were observed from the air, but rough terrain and lack of climbing aids prevented prospecting in the area. The plotted location of the Churchill Occurrence was also overflown but no veining or Cu alteration was observed.

In summary, a total of 13 samples were collected across the Toro property in 2021 with grades ranging from sub anomalous to 1.46% Cu. Cobalt values were significantly anomalous at the Ho occurrence. Anomalous Ba was characteristic of samples collected at the John occurrence. Manganese is also anomalous in samples from both the John and Ho occurrence.

## 8.0 ASTER ALTERATION MINERAL MAPPING - RESULTS

The ASTER sensor is a spectral imaging instrument located on-board the EOS/Terra satellite which was launched by NASA in December 1999. ASTER has been designed to acquire land surface temperature, emissivity, reflectance, and elevation data and is a cooperative effort between NASA and the Japanese Ministry of Economy, Trade, and Industry (METI). ASTER consists of three separate subsystems, each acquiring data from different regions of the electromagnetic spectrum (VNIR, SWIR and TIR). Each ASTER scene covers an area of 60×60 $km^2$.

The VNIR bands have a spatial resolution of 15 m, SWIR bands 30m and the TIR bands 90 m. An additional backward-looking near-infrared band provides stereo coverage. The ASTER channels are more contiguous in the short wave infrared region than those of Landsat, yielding increased accuracy in the spectral identification of rocks and minerals (*Gabr et al. 2010*). **Table 3** provides a summary of band and wavelength information for the ASTER sensor.

ASTER Users Handbook

| Subsystem | Band No. | Spectral Range (μm) | Spatial Resolution, m | Quantization Levels |
|---|---|---|---|---|
| VNIR | 1 | 0.52-0.60 | 15 | 8 bits |
| | 2 | 0.63-0.69 | | |
| | 3N | 0.78-0.86 | | |
| | 3B | 0.78-0.86 | | |
| SWIR | 4 | 1.60-1.70 | 30 | 8 bits |
| | 5 | 2.145-2.185 | | |
| | 6 | 2.185-2.225 | | |
| | 7 | 2.235-2.285 | | |
| | 8 | 2.295-2.365 | | |
| | 9 | 2.360-2.430 | | |
| TIR | 10 | 8.125-8.475 | 90 | 12 bits |
| | 11 | 8.475-8.825 | | |
| | 12 | 8.925-9.275 | | |
| | 13 | 10.25-10.95 | | |
| | 14 | 10.95-11.65 | | |

**Table 3**: ASTER spatial, spectral and radiometric resolution (http://www.pancroma.com/downloads/aster_user_guide_v2.pdf)

ASTER can acquire data over the entire globe with an average duty cycle of 8% per orbit. This represents acquisition of about 650 scenes per day that are processed to three different levels based on final product (Level-1A, 1B and 1T). All processed scenes are transferred to the Earth Observing System Data and Information System (EOSDIS) archive at the EROS Data Center's (EDC) Land Processes Distributed Active Archive Center (LP-DAAC) for storage, distribution, and processing to higher-level data products. All ASTER data products are stored in the Hierarchical Data Format (HDF-EOS).

ASTER level 1B products (*used in this study*) represent registered radiance at the sensor product and as such contain radiometrically calibrated and geometrically co-registered data for the acquired channels. Level-1B data is produced by applying the radiometric calibration and geometric correction coefficients to the Level-1A data files. Further image pre-processing is required to generate surface

reflectance and emissivity multiband imagery that is necessary for mineral mapping and analysis. Scenes used for mineral mapping must predate April 30, 2008 when SWIR sensor overheating began resulting in erroneous data for the 6 SWIR bands.

One minimally cloud covered Aster Level 1B Scene was acquired for the Toro claim block (**Fig. 14**). The mapping area is characterized by moderate ice cover in the central portion of the claims and moderate vegetation cover at lower elevations. These image feature types, in addition to topographic shadow will significantly reduce the surface area over which spectral analysis can be carried out. The imagery was acquired on September 11, 2001 and the Canadian Digital Elevation Data (CDED) 30 m resolution DEM was acquired and used to orthorectify the ASTER Scene. Note that Crosstalk is an effect in ASTER imagery caused by data signal leakage from band 4 into adjacent bands 5 and 9. A cross talk correction is applied using open source software (ERSDAC Crosstalk 3).

Other necessary pre-processing steps after data import includes (i) Image orthorecification using available DEM, (ii) Layer stacking into VNIR-SWIR 9 band layer stack (resampled to 30 m resolution) and TIR 5 band layer stack (90 m resolution), (iii) Atmosphere Correction for VNIR-SWIR data to generate surface reflectance data (iv) Thermal atmospheric correction for TIR data to generate emissivity data (vi) trimming and mosaicking data to the Toro Claims and (vii) Snow, cloud and vegetation Masking.

The VNIR-SWIR image was atmospherically corrected using the module fast line-of-sight atmospheric analysis of spectral hypercubes (FLAASH) in ENVI 5.3. FLAASH uses MODTRAN4 radiation transfer models for the calculations. These models have been shown to be better than other atmospheric correction techniques for hydrothermal mineral mapping.

*Band Ratio and Logical Operators*

Selected ASTER VNIR-SWIR and TIR band ratios and logical operators are extremely effective in mapping hydrothermal alteration for reconnaissance or early stage exploration. **Table 3** summarizes various band ratio and logical operators used in this study to map specific alteration minerals. All operators listed in the table were used to generate mineral probability maps, however the following discussion focuses only on minerals that yielded credible anomalies (gossan, silica and general clay). Note vegetation was masked out of final data products to avoid generation of false anomalies.

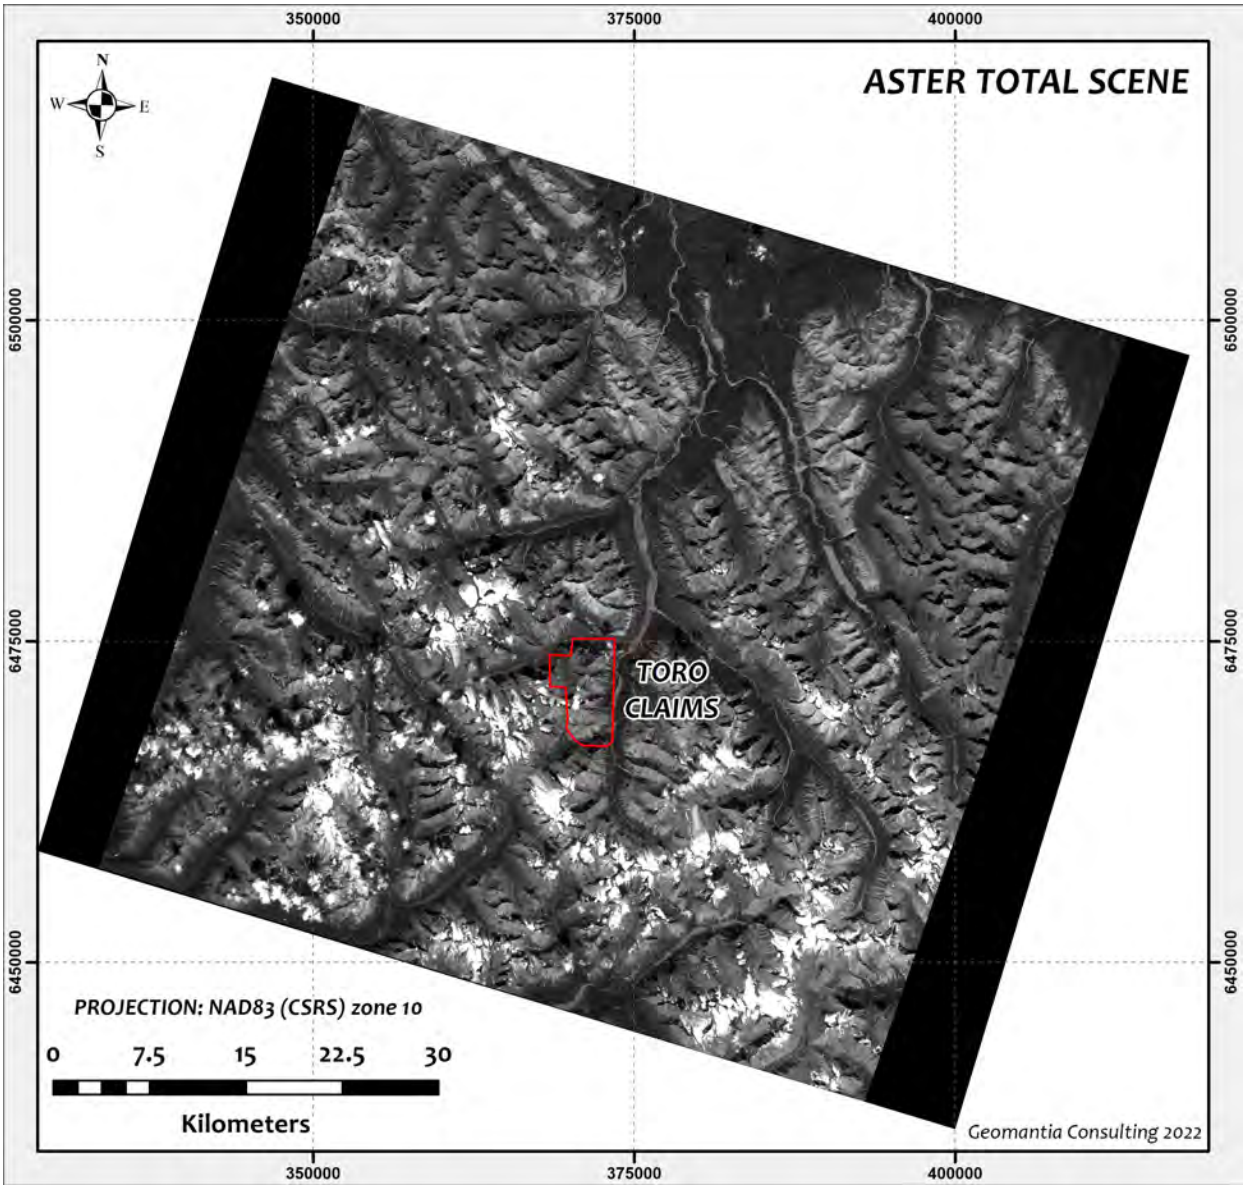

**FIGURE 14:** ASTER multispectral imagery scene overlapping with Toro claims.

Vegetation has a spectral response that overlaps with clay minerals that are identified using absorption and reflection features in the SWIR portion of the electromagnetic spectrum.

| Alteration Mineral | Band Ratio/Logical Operator |
|---|---|
| *VNIR-SWIR* | |
| **Hematite – Goethite** | **B2/B1** |
| Kaolinite | B4/B6 |
| Sericite | (B5+B7)/B6 |
| **Clay General** | **(B5*B7)/(B6*B6)** |
| Phyllic | B4/B7 |
| Muscovite/Illite | B7/B6 |
| Carb/Chlorite/Epidote | (B7+B9)/B8 |
| Epidote/Chlorite/Amphibole | (B6+B9)/(B7+B8) |
| | |
| *TIR EMISSIVITY* | |
| Quartz Rich Rocks | B14/B12 |
| **Silica** | **B11/B10** |
| SiO2 | B13/B12 |

**Table 3:** Band ratios and logical operators used for Toro claims.

Mineral probability maps for gossan, clay and silica alteration are presented in **Figures 15-17** and a summary map of all alteration targets is presented in **Figure 18**. Where the intensity of alteration is strong image classification is divided into medium and high probability groupings. In contrast, where alteration intensity is weakly to moderately developed, a single probability classification is used.

Important observations include:

1. A significant gossan anomaly is present immediately west of the Toro mineral occurrence. This may be spatially coincident with iron oxide development at the Paleozoic/Proterozoic unconformity surface. A smaller gossan anomaly occurs ~ 1 km south west of the Ho occurrence.
2. Numerous zones of clay alteration are located adjacent to diabase dykes, the most well developed clay anomalies occur between the Toro and Churchill occurrences.
3. Nine areas of silica alteration are present in the Toro claims including a cluster of silicified zones ~ 1.5 km north of the Ho occurrence, immediately southwest of the Ho occurrence and associated with known Cu mineralization sampled in 2021, a large anomaly immediately west of the Toro occurrence and several zones located in between the Toro and Churchill occurrence.

All mineral alteration targets identified warrant field follow-up.

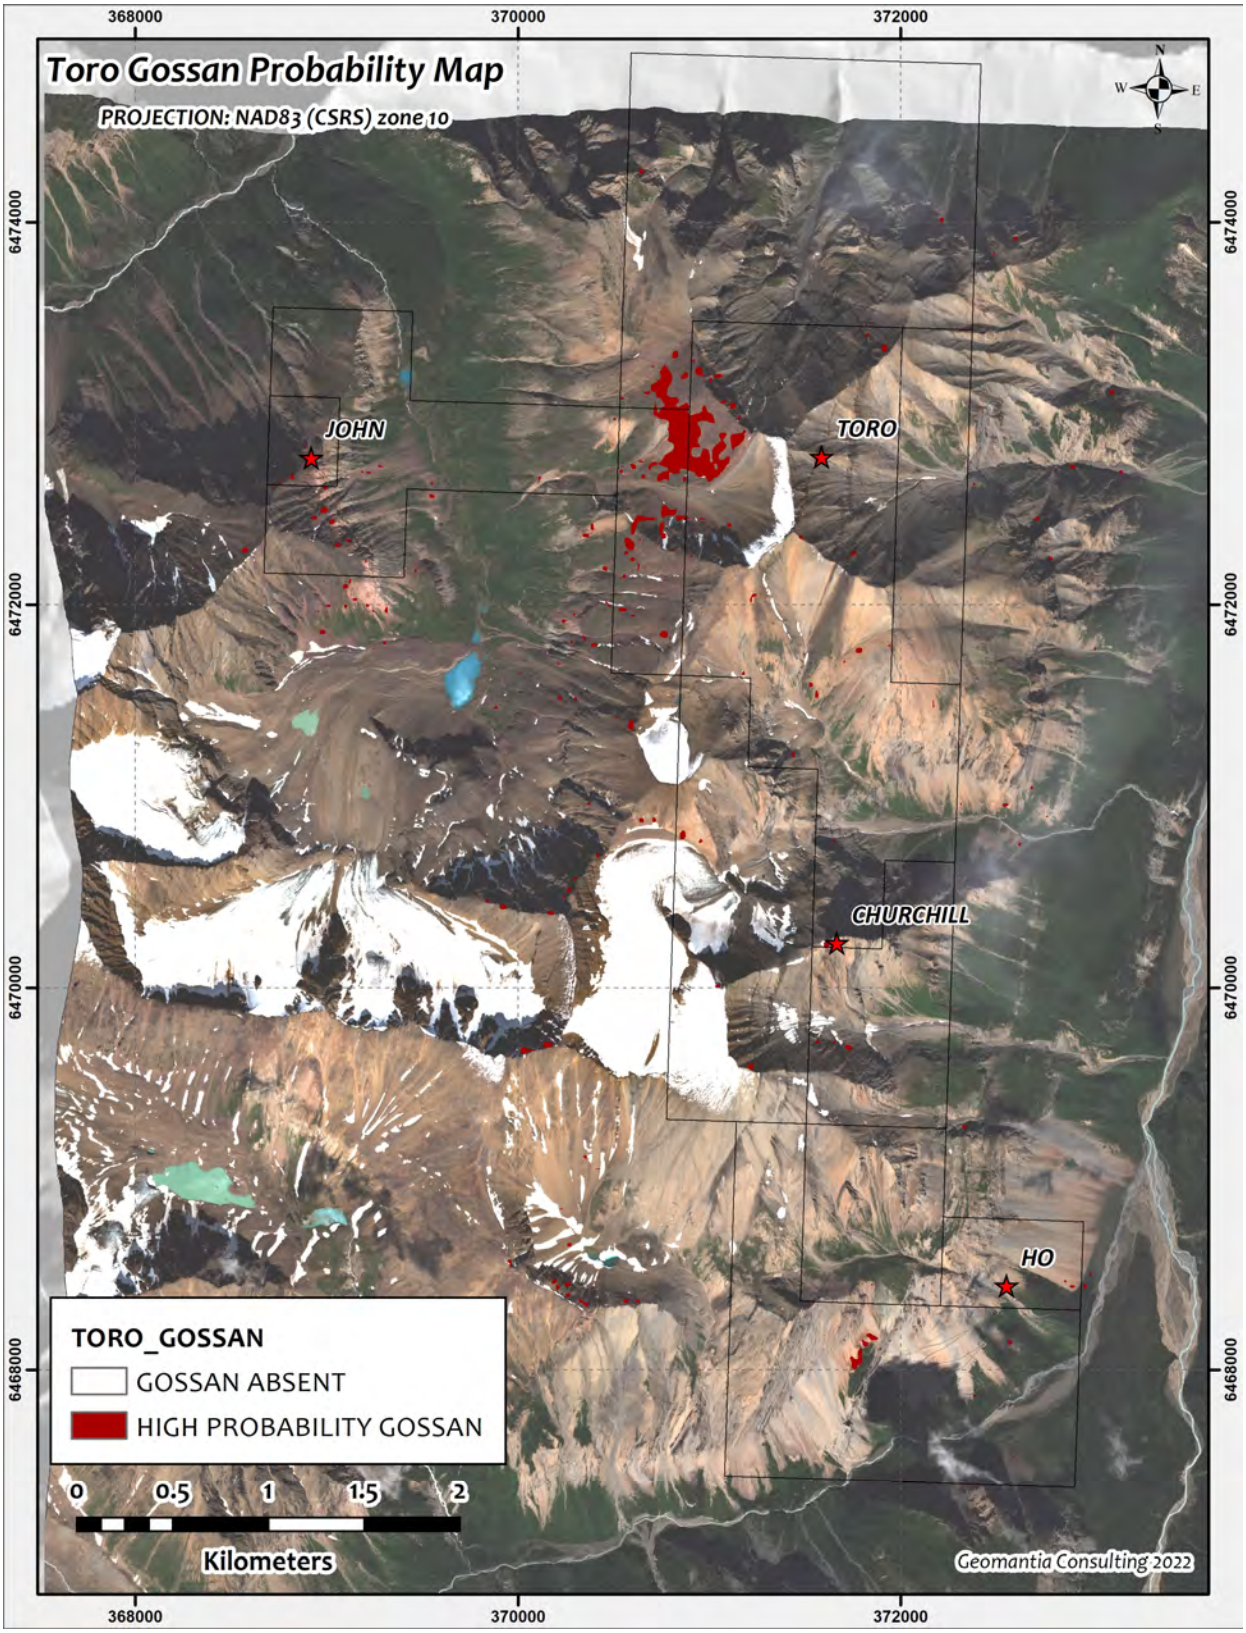

**FIGURE 15:** Gossan anomaly probability map, Toro Property.

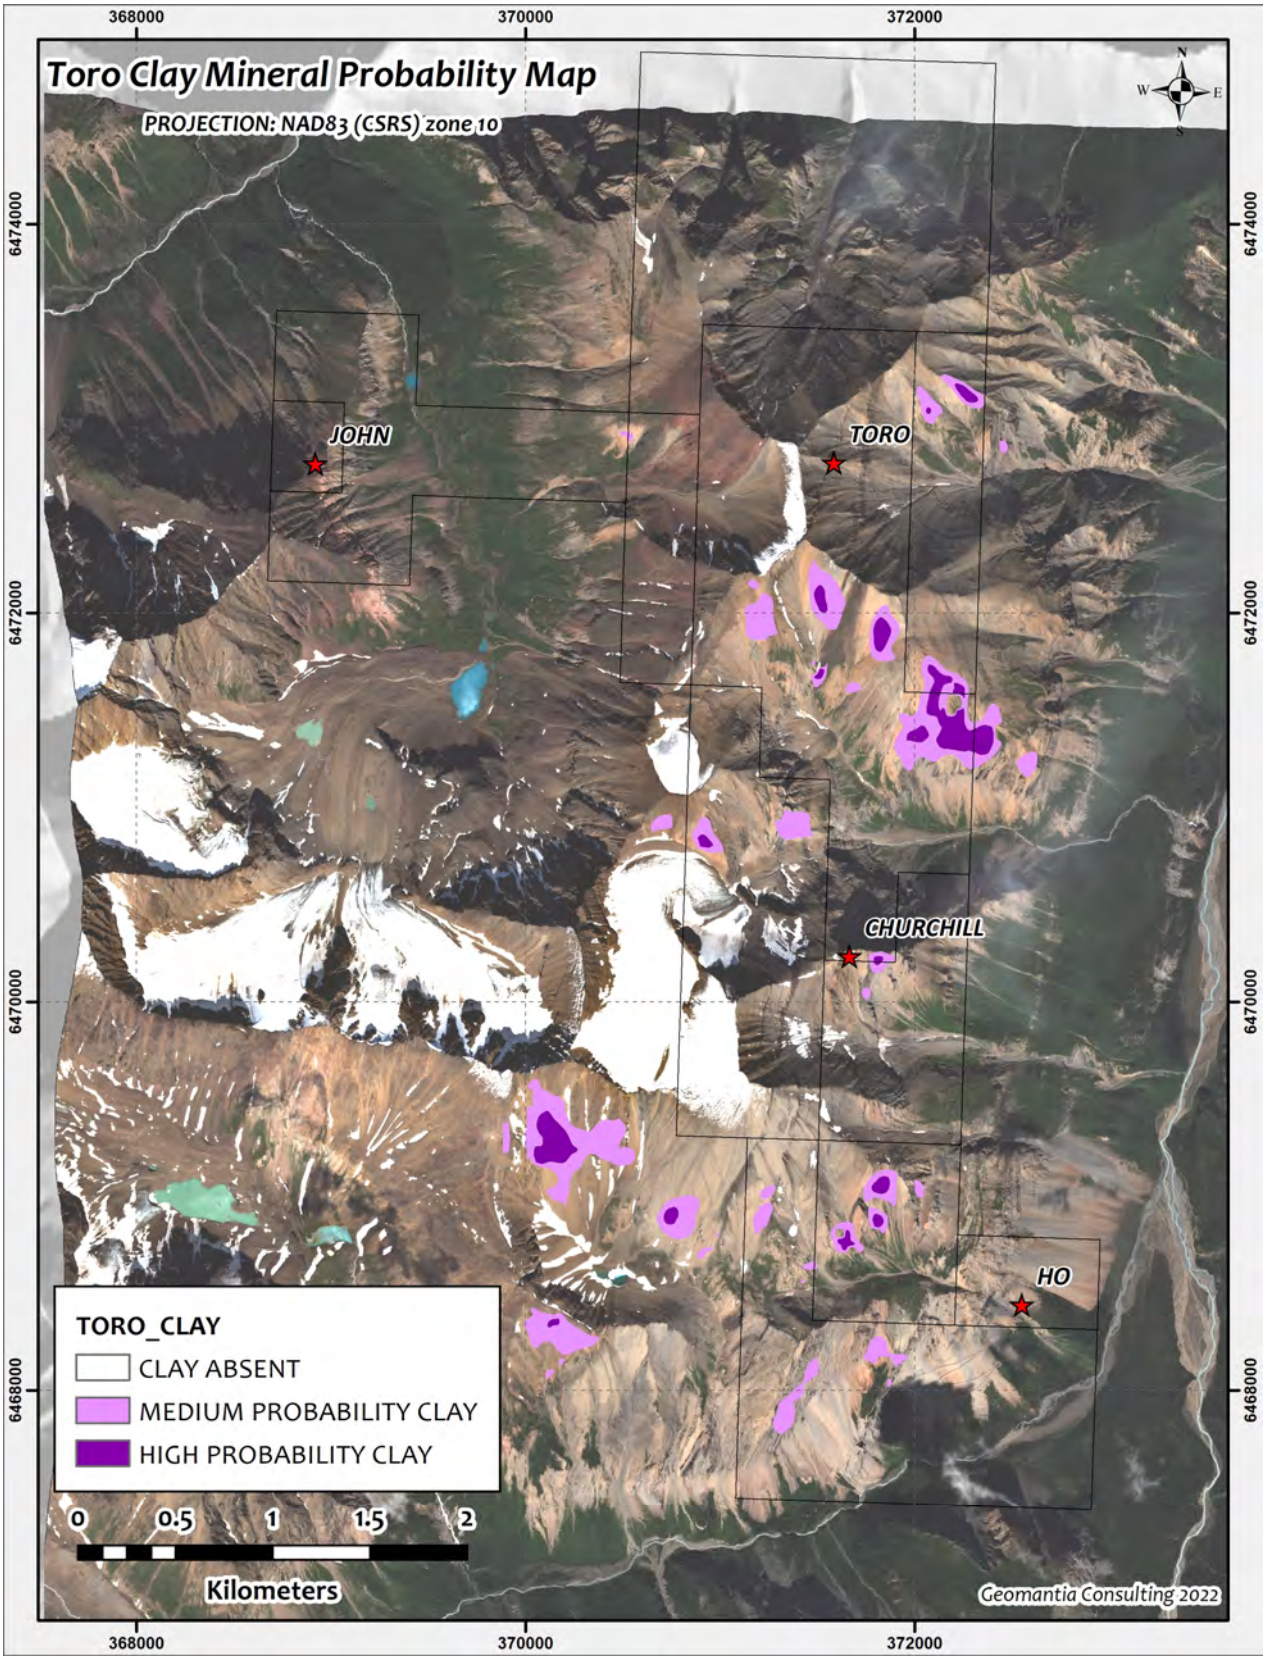

**FIGURE 16:** Clay anomaly probability map.

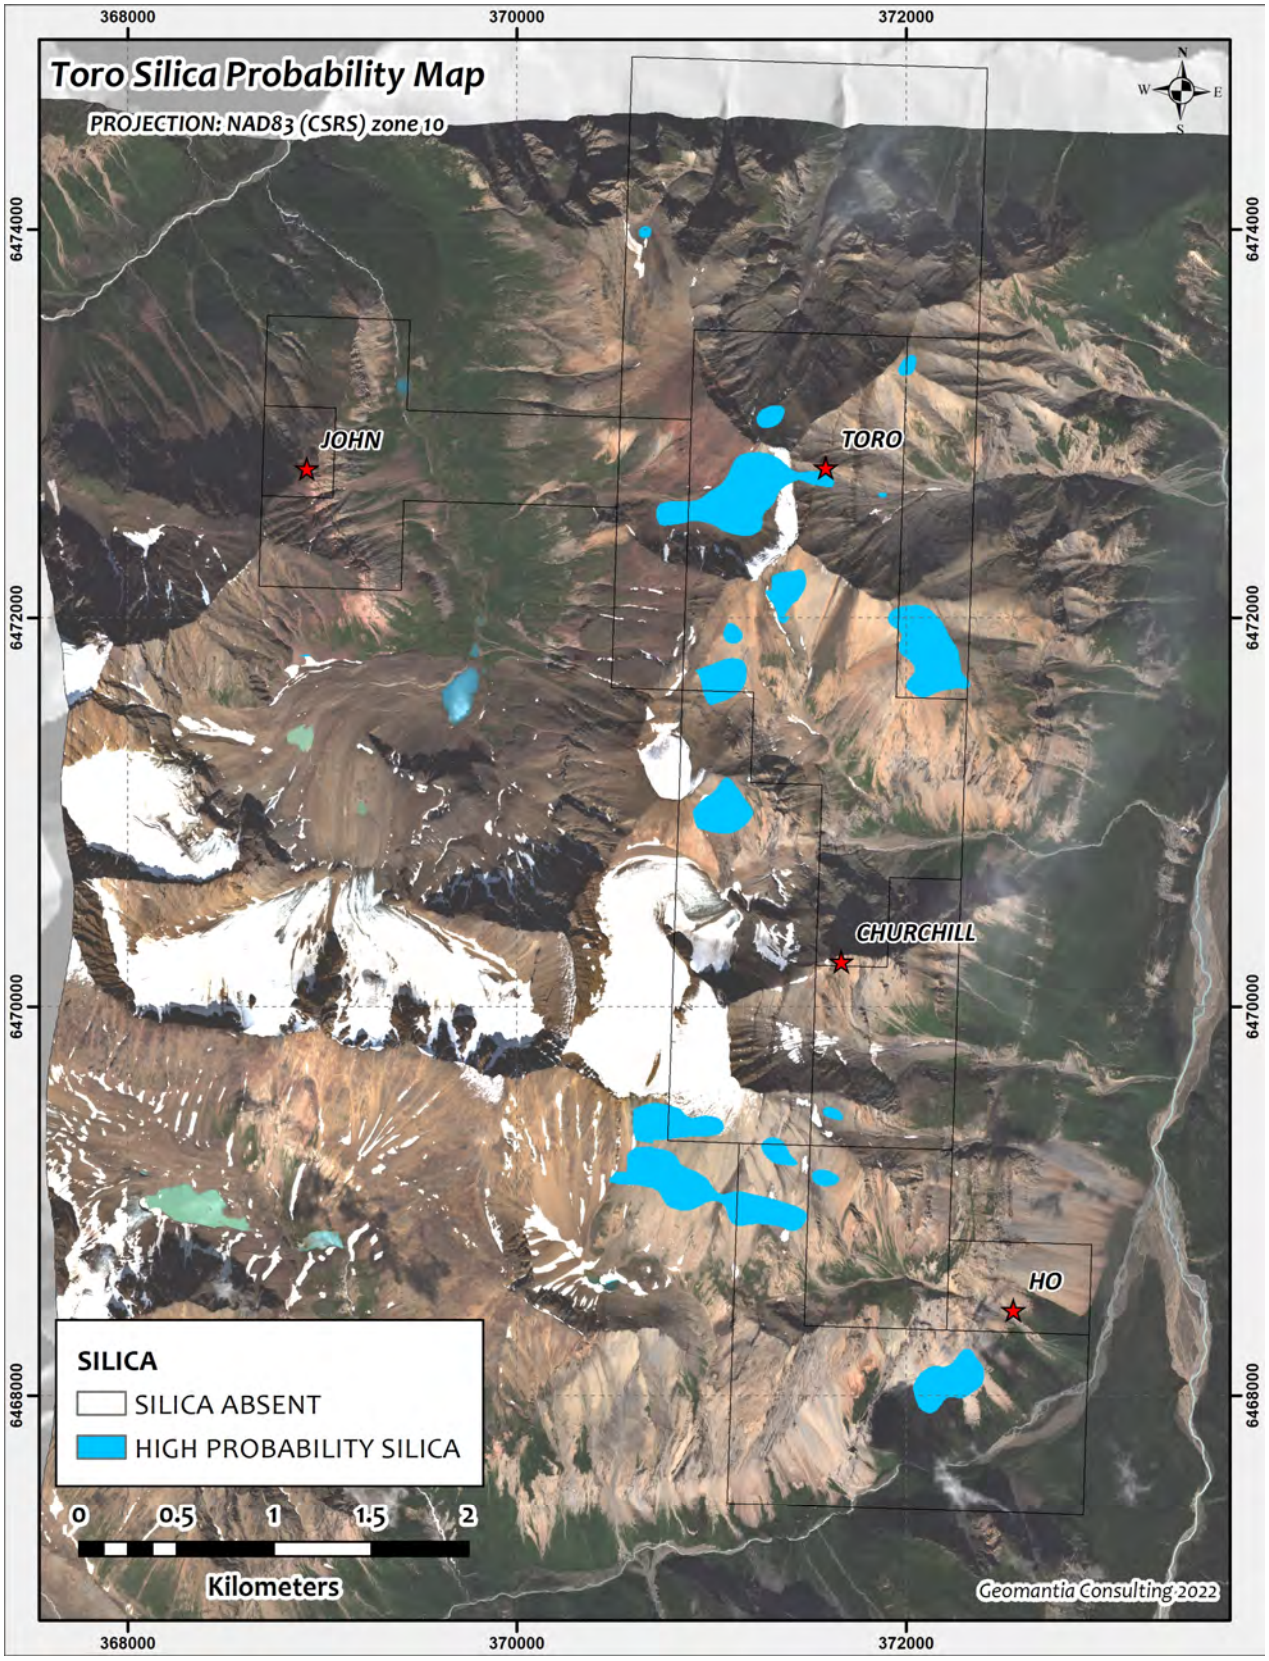

**FIGURE 17:** Silica anomaly probability map.

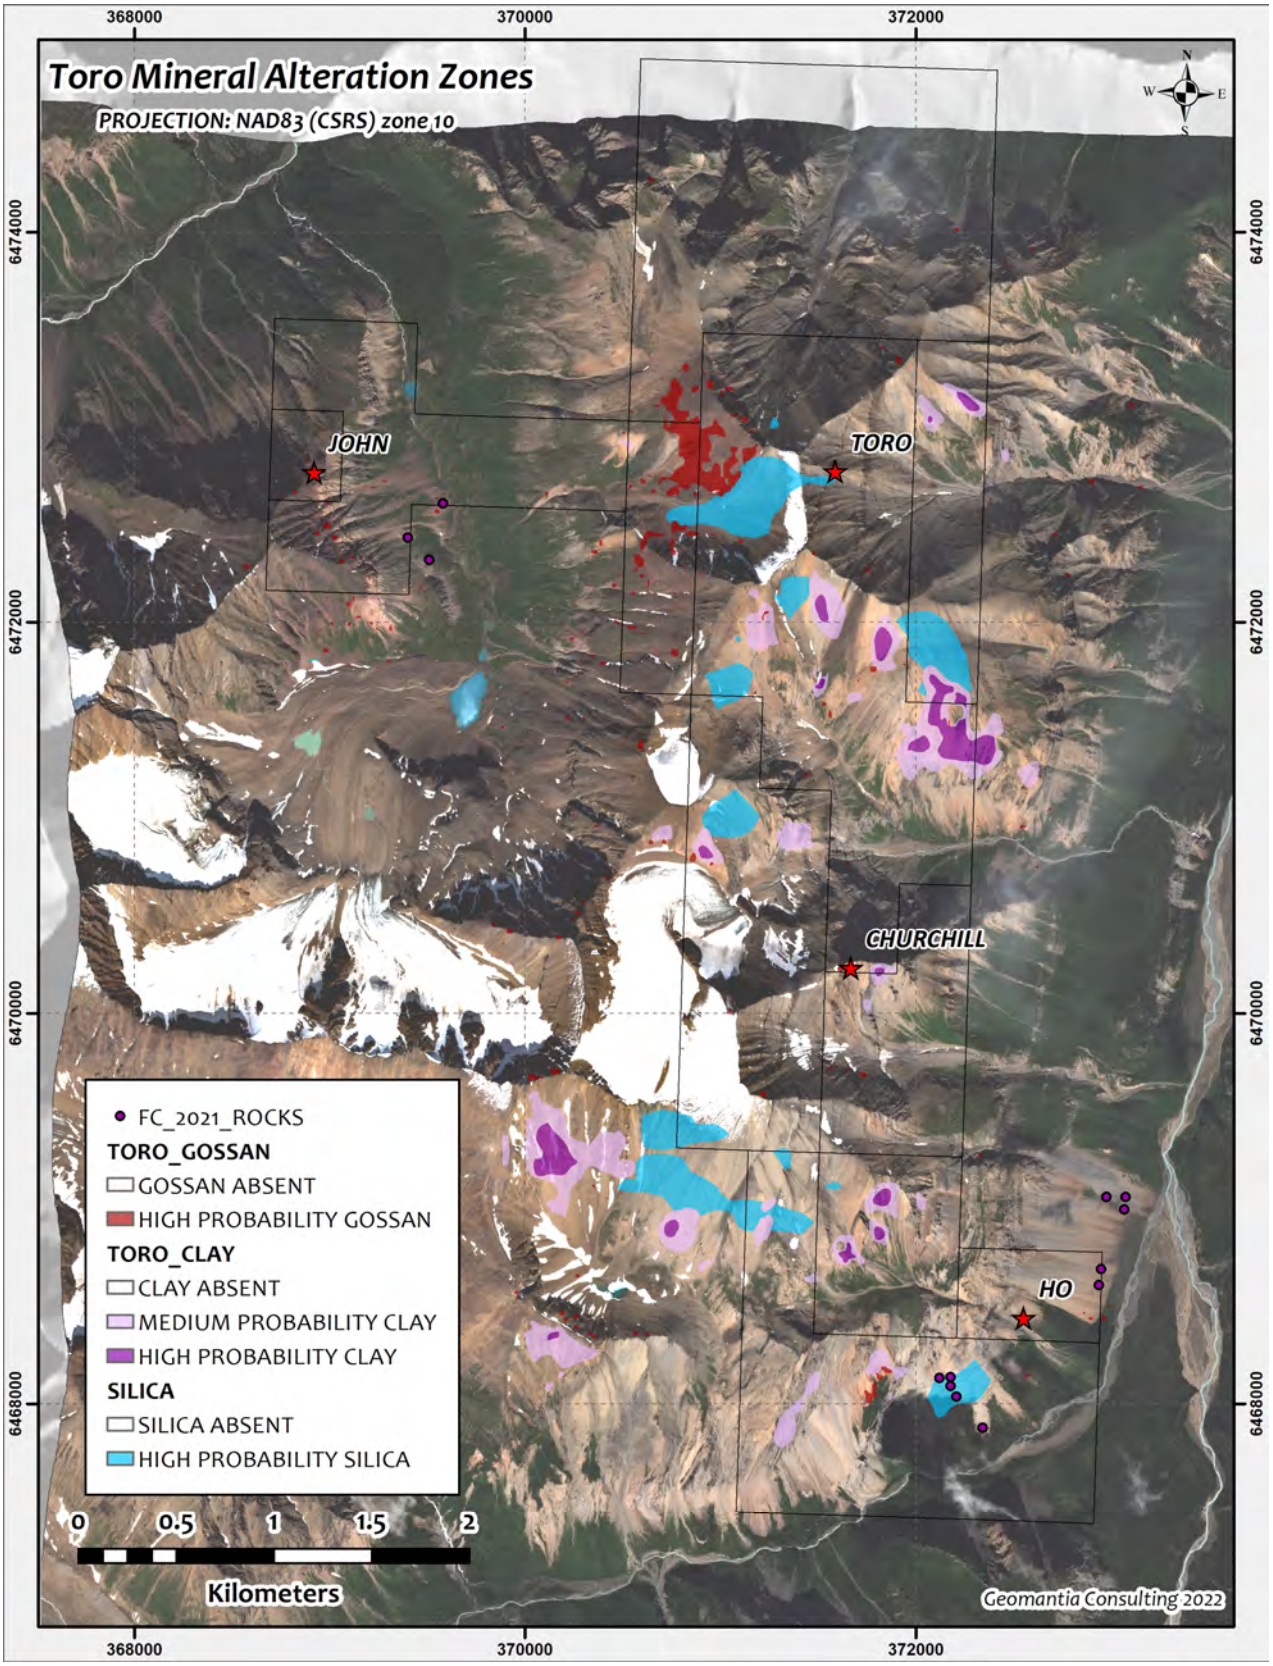

**FIGURE 18:** Summary of mineral alteration targets, Toro Property.

## 9.0 SUMMARY AND RECOMMENDATIONS

Mineralization encountered within the Toro claims consists of copper-bearing quartz iron carbonate veining hosted in Proterozoic carbonates. A spatial correlation exists between this vein-hosted mineralization and the presence of Neoproterozoic diabase units. No data currently exists demonstrating a temporal relationship, however given the spatial coincidence of the two features and exploitation of similar structures, it is plausible they are genetically related. Reconnaissance prospecting during 2021 resulting in collection of 13 samples with Cu values ranging from sub anomalous to 1.46 % Cu.

ASTER multispectral satellite imagery was used to map hydrothermal alteration within the Toro claims. Numerous zones of anomalous gossan, clay and silica were defined that warrant field follow-up.

Key recommendations include:

1. Structural/stratigraphic mapping of the Toro claims (1: 5000) scale, with a focus on (i) identifying Jurassic-Cretaceous deformation and its' intensity (ii) understanding structural controls on vein-hosted Cu mineralization.
2. District-scale gravity survey
3. Unmanned Aerial vehicle photogrammetry surveys over the Toro claims to assist with detailed mapping and 3D modelling of known zones of copper mineralization.
4. Reconnaissance of newly defined ASTER alteration anomalies.

Respectfully submitted,
Geomantia Consulting

## APPENDIX I

## AUTHOR'S STATEMENT OF QUALIFICATIONS

## STATEMENT OF QUALIFICATIONS

I, Venessa R.C. Bennett, geologist, with business and residential addresses in Whitehorse, Yukon Territory and, hereby certify that:

1. I graduated from the Macquarie University, Sydney, Australia in 1996 with a B.Sc. (Hons) in geology, in 2008 from Memorial University of Newfoundland with a Ph.D. majoring in geology and in 2015 from the Centre of Geographic Sciences, Nova Scotia with an advanced diploma in Geographic Information Systems and Remote Sensing.

2. I am a Professional Geoscientist registered with the Association of Professional Engineers and Geoscientists of the Province of Alberta (registration number - 192895).

3. From 1996 to present, I have been actively engaged as a geologist in mineral exploration, geoscience research and government geoscience both internationally and nationally.

4. I was present when the fieldwork reported herein occurred and have interpreted the data resulting from this work.

Venessa R.C. Bennett Ph.D., P.Geo., Adv. Dip GIS/RS

# CERTIFICATE VA21244896

Project: Muskwa Project

This report is for 194 samples of Rock submitted to our lab in Vancouver, BC, Canada on 13-SEP-2021.

The following have access to data associated with this certificate:

| | | |
|---|---|---|
| ROBERT A. CAMPBELL | PETER HAWLEY | GORDON HENRIKSEN |

## SAMPLE PREPARATION

| ALS CODE | DESCRIPTION |
|---|---|
| WEI-21 | Received Sample Weight |
| LOG-21 | Sample logging - ClientBarCode |
| CRU-31 | Fine crushing - 70% <2mm |
| SPL-21 | Split sample - riffle splitter |
| PUL-31 | Pulverize up to 250g 85% <75 um |
| LOG-23 | Pulp Login - Rcvd with Barcode |
| CRU-QC | Crushing QC Test |
| PUL-QC | Pulverizing QC Test |

## ANALYTICAL PROCEDURES

| ALS CODE | DESCRIPTION | INSTRUMENT |
|---|---|---|
| ME-OG62 | Ore Grade Elements - Four Acid | ICP-AES |
| Cu-OG62 | Ore Grade Cu - Four Acid | |
| Au-ICP21 | Au 30g FA ICP-AES Finish | ICP-AES |
| ME-ICP61 | 33 element four acid ICP-AES | ICP-AES |

This is the Final Report and supersedes any preliminary report with this certificate number.Results apply to samples as submitted.All pages of this report have been checked and approved for release.

# CERTIFICATE OF ANALYSIS VA21244896

## CERTIFICATE COMMENTS

### LABORATORY ADDRESSES

Processed at ALS Vancouver located at 2103 Dollarton Hwy, North Vancouver, BC, Canada.

| Applies to Method: | | | |
|---|---|---|---|
| Au-ICP21 | CRU-31 | CRU-QC | Cu-OG62 |
| LOG-21 | LOG-23 | ME-ICP61 | ME-OG62 |
| PUL-31 | PUL-QC | SPL-21 | WEI-21 |

# Gold by Fire Assay

An optimal fire assay flux recipe and rigorous quality control program easily handle problem materials including chromite, base metal sulphides and oxides, selenides, and tellurides.

Choice of crushing fineness, splitting technique and pulp size can all affect the analytical outcome of fire assay gold methods. Discuss with your local ALS laboratory for more information.

| CODE | ANALYTE | RANGE (ppm) | DESCRIPTION | PRICE PER SAMPLE |
|---|---|---|---|---|
| **Trace Level** | | | | |
| Au-ICP21 | Au | 0.001-10 | Au by fire assay and ICP-AES.<br>30g sample | $22.55 |
| Au-ICP22 | | | 50g sample | $26.60 |
| Au-AA23 | | 0.005-10 | Au by fire assay and AAS.<br>30g sample | $21.75 |
| Au-AA24 | | | 50g sample | $25.85 |
| **Ore Grade** | | | | |
| Au-AA25 | Au | 0.01-100 | Au by fire assay and AAS.<br>30g sample | $22.15 |
| Au-AA26 | | | 50g sample | $26.15 |
| Au-GRA21 | | 0.05-10,000 | Au by fire assay and gravimetric finish.<br>30g sample | $27.95 |
| Au-GRA22 | | | 50g sample | $33.55 |

ALS Minerals

## GEOCHEMICAL PROCEDURE

# ME- ICP61

## TRACE LEVEL METHODS USING CONVENTIONAL ICP- AES ANALYSIS

### SAMPLE DECOMPOSITION

**$HNO_3$ -$HClO_4$ -HF-HCl digestion, HCl Leach** (GEO-4ACID)

### ANALYTICAL METHOD

**Inductively Coupled Plasma - Atomic Emission Spectroscopy** (ICP - AES)

A prepared sample (0.25 g) is digested with perchloric, nitric, hydrofluoric and hydrochloric acids. The residue is topped up with dilute hydrochloric acid and the resulting solution is analyzed by inductively coupled plasma-atomic emission spectrometry. Results are corrected for spectral interelement interferences.

**NOTE:** Four acid digestions are able to dissolve most minerals; however, although the term "*near- total*" is used, depending on the sample matrix, not all elements are quantitatively extracted.

| ELEMENT | SYMBOL | UNITS | LOWER LIMIT | UPPER LIMIT | DEFAULT OVER-LIMIT METHOD |
|---|---|---|---|---|---|
| Silver | Ag | ppm | 0.5 | 100 | Ag-OG62 |
| Aluminum | Al | % | 0.01 | 50 | |
